experiments with Peaches and Nectarines, and the wonderful results obtained by intercrossing different varieties:—"A white-fleshed Nectarine, the Elruge, had, with Mr. Williams, produced a seedling with orange flesh, the Pitmaston, which in its turn yielded at Sawbridgeworth a large white-fleshed Peach, and stones from that Peach produced trees with the characters of four generations—viz, the Elruge and Pitmaston Nectarines, the Peach (a child of the latter), and, again, the Pitmaston Orange Nectarine." "It will, I think," he adds, "be seen that my original and rather eccentric idea that old varieties of fruits would reproduce themselves in an improved form if successive generations were raised from seed, has to a great extent been realised."

The paper from which we quote ends with a suggestive hint as to the incurring of the petals as a protection against frost, and the possibility of breeding fruit trees with incurved petals which should be relatively frost-proof. "I may be accused of enthusiasm," says this grand old man, "but I look to the future for new races of fruits with qualities far superior to the old, and the trees of so hardy a nature as to resist some of the unfavourable tendencies of our climate. I have formed this opinion on the solid basis of close observation during a lifetime devoted to the culture of fruit trees in all stages of their growth."

If it were not that our space forbids, we should like to quote more from these two remarkable articles; suffice it to say that they give in brief the history of some of his more remarkable seedling Plums, Pears, Peaches and Nectarines. Of Pears he speaks of 3000 or 4000 varieties, crosses and otherwise—all of interest, but almost hopeless—it is so difficult to raise a fine Pear from seed to ripen when Pears are valuable. "The vagaries of my seedling Pears are productive of amusement, and the hundreds that have not borne of hope."

With Apples, he says he had but little success. He set up the Ribston Pippin as his test, and not one that he raised could surpass or even equal it.

Of Peaches and Nectarines we have already spoken, and what he effected by cross-breeding is known to most of our readers.

In raising of new fruits, as we have seen, Rivers adopted the two plans of selection from seedlings of known origin and of direct cross breeding. In either case exact records were kept—records which we may hope will one day see the light, as their value from a scientific point of view would be very great. Practically speaking, his main aim was to extend the season of particular fruits, and generally to improve their fertility and quality. In the case of the thousands of uncrossed seedlings raised by him only an infinitesimal number were preserved. Rivers' taste was too critically exacting to allow what he thought an inferior variety, or one not better than what we possessed before, to pass muster. Excellence only was perpetuated—the remainder, of mediocre or inferior quality, were made to serve an honourable and useful purpose as stocks.

In raising crosses Rivers followed two distinct plans—1, the self fertilisation or in-and-in breeding, and 2, cross-fertilisation. Most desirable would it be on all accounts if the history and results of all these thousands of experiments should be recorded, for a more valuable series probably never existed. If the experiments were not carried out with so much care and accuracy as in the case of those of Mr. Darwin, yet their vast number and the length of time over which they extended may in large measure compensate for the defects in a scientific point of view. But it must be remembered that Rivers was quite aware of possible defects, and his keen eye and finely-tempered intelligence were excellent guides in the conduct of experiments. Nothing was left to chance, says Mr. Fish in writing on this matter, but the results obtained were the result of studious toil, minute observation, plodding perseverance, skilful experiment, and profound investigation. Hence his successes were no mere chapters of accident, but an onward series of philosophic sequences. The general results of cross-fertilising Peaches and Nectarines, Nectarines and Plums, Plums and Apricots, Apricots and Nectarines, and so forth was, we may repeat, to secure new flavour and qualities, varied constitutions, endless combinations of colour and characteristics.

ORANGE CULTURE, ETC.

In later years Rivers turned his attention to Orange culture under glass, a subject which also formed one of the papers read by him at the London Botanical Con-

gess of 1866. The Orange-house at Sawbridgeworth is truly a lovely sight, but we cannot quite share the enthusiasm which would have us admit the flavour of a home-grown Orange to be equal to that of a St. Michael's.

Ornamental trees and shrubs formed another of Mr. Rivers' hobbies, and his taste for fine varieties and his interest in those that are curious were very noticeable; Planes, Elms, Oaks, Limes, Caraganas, and many others, were the objects of his care and attention. Our own columns contain the record of his observations on these matters, and the writer of these notes has cause to remember with gratitude the information on this as well as on various physiological subjects derived from him.

And now, after such a busy, active life the end has come. Age and diminished strength had paved the way, so much so that for the last four or five years Mr. Rivers lived in quiet retirement. Handsome in person, a fine man physically as well as mentally, Thomas Rivers leaves behind him a memorial that commands admiration, compels respect, and which will stimulate those who come after to lead according to their capacity a life as useful and as honourable as he did.

HARDY ARADS.

ALTHOUGH there is not much in the flowers, or rather spathes, of any of the Arums to commend them except their quaint forms and singularity, *A. italicum* is highly ornamental during the autumn months, owing to the number of fruit-spikes it bears. These are in the form of clubs, the top 6 or 9 inches of which is closely packed, like an ear of Indian Corn, with large rich shining coral-red berries, that, seen without the plant having any foliage and standing straight up from the bare ground, have a peculiar and striking effect. On a strog clump in the herbaceous border here twenty-five of these brilliant fruit-spikes are now standing, and have been much admired for some time past, the dry weather apparently suiting them, as they are finer this year than I ever remember to have seen them before. The leaves are produced during the winter, and attain their full state of development by March or April, and are then exceedingly ornamental, as indeed they are all through their growth—the deep glossy green of their foliage showing up in pleasing contrast with the yellow veins by which it is traversed. The spathe is of a yellowish-green colour, and when fully expanded is from 4 to 5 inches across, or about double the size of the common Arum of our banks and hedgerows, as is also the spadix; so that even without the spikes of berries it is a very desirable plant to cultivate, and one that should be in every mixed or herbaceous border.

It is readily increased by division, which may be done almost at any time, but is best carried out now, just as the leaves are forming, as then they have a good chance of establishing themselves and getting strong before their season for flowering arrives. Any one obtaining the corms at once would, by planting them in deep rich soil, have the pleasure of seeing them bloom and produce their scarlet berries next summer, when if left to themselves they soon spread and form fine bold masses, that are sure to attract notice. The most remarkable of all the hardy Arums is *A. crinitum*, a native of Minorca, which from its grotesque character is well adapted for growing in the wild garden or fernery, or similar positions, where it can be afforded a loose sandy soil with plenty of moisture at the root. The leaves of this, instead of being entire, like *A. italicum*, are divided, much after the manner of the more recently introduced *Amorphophallus Rivieri*, which it greatly resembles. In favourable situations it grows to a height of from 2 feet to 2 feet 6 inches, and produces very large spathes, which, when fully expanded, are from 8 inches to 10 inches across, and a foot or so in length, the interior being lined with dark-coloured hairs, and dotted or mottled over with black spots, which, with the large hirsute spadix, makes it a most curious-looking object, and a very interesting one to examine. The tube of the spathe, which is very large and long, is not erect like the other Arums, but has a peculiar bend near the top just before it expands, thus adding to the singularity of its appearance. When dying off it emits a carrion-like smell of sufficient strength to attract flies in quest of a place to deposit their eggs, some of which in their descent of the neck of the spathe for the purpose of doing so are enwrapped and

made prisoners much in the way they are by the Sundews and other so-called carnivorous plants.

Arum Dracunculis is likewise a most interesting-looking plant to cultivate, and one that is altogether of such a striking character as not to be passed by without notice. The stem of this, which is flesh-coloured, is mottled or spotted over like the skin of a snake, and this peculiarity has suggested for it the name of the Snake-plant; but this is not the only one of its attractions, as it has handsome pedate leaves, and produces a very long spathe of a deep chocolate colour on the inside, with a spadix tapering and terminating in a fine point. Although a native of Southern Europe this species is quite hardy with us, and does well in shady places in loose boggy soil that has been well drained. Unfortunately, at certain stages of development it emits an offensive odour, but this is not continuous, as it may sometimes be detected on passing, when perhaps five minutes or so later nothing of it remains. To those in search of uncommon-looking plants I can strongly recommend the two above-named, as also *Amorphophallus Rivieri* [figured in our columns, 1873, p. 609]; but of the hardness of the latter I have as yet had no experience, not having ventured to leave it out for the winter, neither have I had the pleasure of seeing it bloom. We have as yet been using it as a dot plant for the centres of circular beds, and to grow amongst Ferns and other foliage subjects in the greenhouse, where, from its stately Palm-like habit, it has been greatly admired. J. S. [Why not try the most curious of all, the *Amorphophallus campanulatus*, or the *Godwinia*, as sub-tropical plants, or where a heated outdoor border could be employed. EDS.]

PRINCE'S PARK, LIVERPOOL.

THE inhabitants of Liverpool are indebted for this Park to that enlightened and philanthropic gentleman, the late Richard Vaughan Bates, of The Dingle, near Liverpool, who in 1843 purchased about 100 acres of land from the then Lord Sefton, and had the same laid out into what now forms Prince's Park, from plans prepared by that eminent landscape gardener, the late Sir Joseph Paxton.

In designing the Park, a portion of the land round the margin was reserved for building sites, on the whole of which for some years now a superior class of family residences have been erected, principally owned and occupied by the leading merchants, &c., of the town, this being quite a fashionable or West-end part of Liverpool. It is worthy of mention here that it is from an annual ground-rent levied upon this building land as sold off that the income for maintaining the whole of the Park expenses is solely derived, and it is in consideration of the resident having to pay this ground-rent (which is compulsory on purchase of land) that a small portion of the Park (about 3 acres) is called the "private grounds."

This private enclosure is worked out on such a judicious scheme that computation is completely baffled, and the ordinary idea would be that the garden is three times as large as it really is. This portion of the park is set apart for the exclusive use of the resident families, each family being entitled to one key. In the other portions of the Park the general public are admitted, and on fine days, especially Sundays, thousands avail themselves of the privilege, and it is to be hoped duly appreciate the great boon thus provided for them entirely free of cost, as not a single shilling goes out of the rates towards the expense of this Park, as in the case of other parks under corporate management. As one illustration out of many of the spreading growth of this great commercial town it may not be out of place to add that when Prince's Park was first designed it was what would be called "in the country" from Liverpool, whereas now it is becoming rapidly surrounded by the town—a fact that vastly increases the difficulty of general improvement. At the north or main entrance direct, *via* Prince's Road, from Liverpool, there is a commodious lodge erected for the manager, Mr. Mason, under whose astute management the name and reputation of Prince's Park stand second to none in the kingdom for good order, general arrangement, and refined taste and ideas.

The health and arrangement of the shrubs and trees, the selection, propagation, and arrangement of the various tribes of plants that are used for spring and summer bedding, especially the latter, are particularly worthy of mention; indeed, it may be truly said that Prince's Park is the "Battersea of the North," for in no other place that we know of is carpet bedding

attempted on so large a scale or so skillfully executed under the reverse of a favourable climate or circumstances. It is as well to observe that the effects of the inclement season on tender plants have been felt to some extent here, as elsewhere, but only on close inspection is it possible to trace defects which are more than compensated for when it is considered that any little eyesore in lack of growth amongst tender things is only of a very comparative character.

Of noteworthy objects may be mentioned a row of specimen scarlet Thorns, of remarkable growth and luxuriance, on the road leading from Sefton Park to Liverpool. St. Paul's Church, built for Dr. McNeil, late Dean of Ripon, is also an object that attracts the eye looking westward from the Park, and stands out in bold relief from all its surroundings. We merely mention this as an extraneous object, having no connection with the Park, except its position as a noteworthy edifice of some notoriety and importance. Returning to Mr. Mason's house we notice an irregular sweeping belt of evergreen trees and shrubs, the object of which is apparently to act as a protection to a beautiful chain border, which we shall notice presently, as well as to form an inclosure on the north side of what we may call a sort of American garden, which has been strikingly and very tastefully laid out by Mr. Mason. One is here struck by the combination of ideas so happily concentrated together that they harmonise with one another, and at the same time impart a bold outline to the landscape, and secure the paramount utility of protection. This American garden is of an undulating character, and is here and there relieved by raised beds in grass, the centre plant in each being a scarlet or pink Thorn, or some other striking object. The beds are filled with hybrid and Ponticum *Rhododendrons* mixed, some of which are edged with hardy Heaths, others with a mixed edging of such things as are known to be proof against a rough climate. As a rough-weather plant, either for individual purposes or for grouping, nothing seems to equal *Pernettya mucronata*. Here it is planted in the worst situation, and is always fresh and lively in appearance. An isolated circle of scarlet *Pelargoniums*, occupying a low spot in the centre of a little valley, can be seen from all points of vantage, and illustrates the advantage of strong colours as being peculiarly fitted for distant planting, the strength of colour being chosen in proportion to the effect distance is known to have in subduing colour.

Other outside portions of the park have undergone a complete reformation at the hands of Mr. Mason, particularly that portion adjacent to the Dingle Cricket Ground, which, as may be guessed, is a great resort for the youth and beauty of Liverpool during the greater part of the season.

As we propose to deal first with that portion of the Park which is open to the general public, we must now retrace our steps and examine the chain border, to which reference has been made elsewhere.

The border is a continuous chain of *Cerastium*, forming a series of oblongs each 12 feet by 36 feet, and circles 12 feet in diameter; the circles being raised in grass, and a specimen *Hodgins' Holly* being planted in the centre of each. The oblong spaces are devoted to flower-beds, with a margin of grass 18 inches wide between the *Cerastium* and the beds. The planting is artistically carried out, as follows:—Oblong No. 1 is a design of seven 2 feet 6 inches circles of *Pelargoniums*, four being *Golden Superb Nosegay* and three *Miss Kingsbury*, with a *Centauria* and *Beet* in the centre of each respectively; the groundwork *Viola Blue Bell*, surrounded by a band of *Golden Feather* edged with *Echeveria secunda glauca*.

No. 2 is a design of nine beds, planted in variety with yellow *Tagetes*, blue *Lobelia*, and so on.

No. 3 is divided into seven beds, where a very showy effect is produced with *Blue Perfection Fansy* and *Pelargonium Memnon*.

No. 4 is planted in bands of *Miss Kingsbury Pelargonium* (old plants), *Perilla nankinensis*, *Pelargonium Lancashire Witch*, *Viola Blue Bell*, edged with *Golden Superb Nosegay Pelargonium*.

No. 5 is formed into diamonds and half-diamonds, planted principally with blue *Lobelias*, *Golden Feather*, crimson *Verbenas*, *Mesembryanthemums*, &c.

No. 6 is a design of seven beds, planted effectively with scarlet *Pelargoniums*, *Calceolarias*, *Violas*, &c.

No. 7 is planted in bands, the centre line being *Cleopatra Pelargonium*, with a row of *Beet* on each side, followed by *Calceolarias* and *Violet Hill Pelargonium*, and finished off with *Gnaphalium*.

Proceeding *en route* to Sefton Park, the visitor may enter a gate on the east side, and stroll leisurely by the side of a magnificent lake, which is rich in the beautiful Lily, *Nymphaea alba*. From this side the lake there is an excellent view of the "private" gardens and grounds, where the rich colours of the bedding plants blend agreeably with one another in the cool eventide, mingled with the faint rays of the setting sun—a perfect Paradise in the distance, ensconced within a labyrinth of scenery that would need the pen of Milton to justly pourtray. Passing on by the lake side there is a gate on the right hand, which is the entrance to the private gardens from this side. On entering the private grounds the observing visitor is at once struck with the ever-changing scenes. Variety seems to have been the preponderating influence throughout, and to this may be ascribed the enlarged ideas of strangers when computing the extent of ground allotted to this purpose. O. H. W.

(To be continued.)

FIG. 106.—ASTILBE BARBATA AS GROWN FOR MARKET.

The Villa Garden.

AUTUMN PLANTING.—As we write, the rain, so long impending and so ardently wished for, is falling. There is a pleasant sweetness in the sound thereof, for the earth is thirsty; and notwithstanding so much rain fell during the summer, the past month of dry weather has drunk up the moisture, and many plants have been flagging for want of it. The spell of dry weather has not been without its uses; it has ripened the wood of fruit and other trees, it has enabled arrears of cleaning to be cleared up, and it has most agreeably softened the relapse of summer into the gloom and decay of autumn. It has delayed planting operations, but they can now be carried out, and it is not too late for executing them.

PREPARATION OF THE SOIL.—If fruit trees or shrubs are to be planted the soil must be prepared for them if they are to succeed. Hundreds of villa residents have taken new residences and found their gardens planted and laid out after a certain fashion. The garden is but a small matter in the estimation of the builder; when the house is completed the garden is attended to—the heaps of refuse soil are levelled, and then planting takes place. How it is

done in the first instance is patent to many of us. A hole is dug, the roots of a scraggy tree are thrust into it, it is filled up, and the work is done. And the plants exist for a time, and then many of them expire of a lingering decline. Surely there must be retribution stored up somewhere against such evil-doers in the walks of gardening.

It is no use to plant trees of any kind unless the soil in which the roots are placed is of a nature to nourish and minister to the well-being of the trees. If it is composed of clay and rubbish, out it must come, and some good loam substituted for it. If the soil be suitable let it be deeply dug or trenched, taking care not to go deep enough to bring up any sour or unkind subsoil. If possible dig in with it any nutritive vegetable refuse or leaf-mould, or any old potting soil.

SELECTION AND CONDITION OF THE PLANTS.—If the planter be unacquainted with fruit trees or shrubs, let him get proper advice as to the most suitable subjects to plant. There is always some one at hand to

give advice if only they be sought for. A proper selection being made, the next thing is to see that the roots of the tree or shrub about to be planted are in the proper condition. And now we come to the necessity that exists for nurserymen frequently transplanting trees and shrubs, so as to induce them to put forth good healthy fibrous roots. The Villa gardener should select his plants at a nursery, and stipulate that they were transplanted the previous autumn. The small fibrous roots so necessary to the well-being of the plants are of the first importance, for it is through what botanists term the "spongioses" at the extremities of these that the plant draws in its nourishment from the soil. If it be necessary to trim the roots, the knife should be used with care; and it should be employed to cut away the main or tap-root, but not the fine hair-like fibres or rootlets, all of which should be carefully preserved.

MODE OF PLANTING.—It appears a simple thing to plant, but there is more in the proper method of doing it than is generally supposed. A big enough hole should be dug to take the roots, and enable them to be laid out in a regular and natural manner. The regulation-sized pits of the unreflecting jobbing gardener must be abjured, and according to the size of

the ball of roots should be the receptacle in which they are to be laid. It should be just deep enough to admit of the upper roots being covered to a depth of 10 inches or so. It is not well to plant too deeply, and it has been remarked that "thousands of young trees perish annually from being planted too deep. In situations exposed to violent winds it may be allowable to plant a little deeper, but it is only meeting one evil by substituting another, and it would be preferable to undergo the expense and trouble of staking the young trees where it is required;" and in order to give the young rootlets as much encouragement as possible, a little fine soil sifted from the refuse of the potting bench, if placed among them, will be found highly beneficial. This done, fill in with the ordinary soil, and tread it firmly about the roots. Should it happen that a time of drought follows the planting, water must be given, and if a little dung and leaves be thrown on the surface round the stem of the trees, they will reap the benefit of it. There is one advantage autumn planting has over spring planting—that it rarely happens the plants and trees suffer from drought.

The best time to plant is a consideration which follows as a matter of course. In a very useful manual issued by the Heatherside Nursery Company it is observed that transplanting may be performed at any time from October to April, according to the nature of the season. It is difficult to give any general rule, but roughly it may be laid down that autumn is the best time for Conifers and evergreens, and spring for such deciduous plants as do not expand their leaves too early. But the canon to be observed is to plant as much as possible during wet or cloudy weather, and to refrain in sunshine, drought, or frost. Such intervals of forced inaction may be profitably employed in settling the spot where each tree is to be planted, in digging the holes, and in providing the compost to be put round the roots when the planting is performed. The Villa gardener should plant as early as possible in the autumn before bad weather, as rain or frost, sets in to disturb his work, and perhaps keeping his garden in a disturbed state during a good portion of the winter. Perchance he may by so doing get the pick of the trees from the nursery; and having planted as recommended, let him stake each tree securely that needs it; and then, levelling the soil, let him leave all tidy and orderly, trusting that the newly introduced trees will in good time shape themselves into sufficient branches and leaves, that rains will not cease to fertilise nor the sunshine to quicken them in the time to come.

ASTILBE BARBATA.

THE accompanying illustration (fig. 106) of this invaluable early-flowering decorative plant, erroneously known under the names of *Spiræa* and of *Hoteia japonica*, was prepared last spring from one of the great number of specimens grown for market by Mr. John Reeves, of Acton, to show to what wonderful perfection it may be grown in a 48-pot. The plant is grown in great quantities amongst the bulbs near Haarlem, where we were told it was a constant source of wonder to the workmen, as, through it not flowering with them, they cannot understand what the English want it for. The English, however, have found out its great value for early forcing, and we could not well do without it. The clumps are now being imported in large quantities, and we shall not have long to wait before the plant makes its appearance in all its elegant beauty in the neighbouring market. Its culture is remarkably simple, and its main requirements may be summed up in three words—heat and moisture.

Apiary.

WINTER MANAGEMENT.—Probably no part of the year is so little understood—certainly our apiaries are, as a rule, very badly managed in the winter; it may arise in part from the fact that our favourites are seldom seen in severe weather, they are therefore neglected. We find upon observation the majority of the stocks in cottage gardens are lost during winter, because they are hived in common skeps, where they cannot be overhauled to find out how they are faring, and whether they are deficient in food; although where we have induced their owners to weigh the stocks in October, and to rapidly feed up those that are too light, they have seldom lost any stocks from actual starvation. Again, cottagers invariably hive every swarm. Many of them are unable to build sufficient comb to store with honey before the winter is on them, they are thus soon de-

stroyed, and are regarded as so much loss, though, in fact, they but seldom do any good if they are hived solely as stocks. If they could be prevailed to add a condemned stock to each in time, then feed them up, so as not to disturb them in the depth of winter, they would make fair average stocks another season.

Many conflicting opinions are to be found amongst bee keepers as to the best plan for wintering their stocks; whilst some declare it is the best plan to allow them to occupy their stands without moving them, others say a dry cellar or cool store-room is preferable. A few winters back we lost many valuable stocks, we believe, from a very simple cause; upon examination the following winter, at stated periods, we always found the hive full of moisture; sometimes the combs at the summit were saturated, and in nearly every instance in our valuable bar-frame hives the combs were mouldy, so that in the spring a great part had to be removed. Then we tried an experiment. Over one hive we placed our tin feeder, and opened the communication to the hive. We afterwards measured the water, which gradually condensed on the cold tin, and found 12 oz. This was from one stock alone. To another wood-hive we placed a match under each corner of the top-board, so as to make a free passage of the heated air to the outside. Both these stocks came out strong and healthy the following spring.

From this experiment we were taught a most useful lesson upon the advantage of ventilation. Now it is a well-recognised fact that bees, if wintered in straw hives, are healthier than in wooden hives. We speak now about keeping them on the stand in the open air all winter. In the extreme north of Scotland, and even in Norway, the bee-keepers never think of taking them from stand or open-air bee-house, as the case may be, and so much is straw thought of for protection that they merely place a covering of that material over them, bound round with an iron hoop from some old cask, to hold it together or to prevent its being blown away in strong winds.

Of course we do not deny the importance of having strong stocks in winter as well as summer; then next to this we advise good ventilation rather than confining them to a close atmosphere filled with moisture. We should recommend lifting the hive from the floor-board, and resting it upon something to raise it at least a quarter of an inch, thus a free ventilation will be secured. Do not for a moment imagine your bees will suffer from cold. Bees are seldom lost from a cold winter if they have good stores and a dry hive. *R.*

Natural History.

THE CUCKOO.—Having seen two paragraphs in your valuable paper respecting the cuckoo, I may mention that I have had the opportunity of proving that the principal food of the cuckoo during the time of their stay in England is the eggs of small birds, which they suck. I never knew them to suck the eggs of the misel-thrush, although I have known them to try; but such is the fury with which the misel-thrush defends its nest that the cuckoo is beaten off in the attempt. In the wooded parts of East Kent, where cuckoos abound, and where thrushes and black-birds are also plentiful, I have found when a boy six or seven nests a day with all the eggs sucked by the cuckoo. Early in the morning you may see the cuckoo flying along the hedges very gently in search of nests, and when they find one they drive off the old bird and commit their depredations. They first make their appearance about April 12 in East Kent, and the 15th in West Sussex on the borders of Hampshire. I have never known or found a bird's nest with the eggs sucked till after the arrival of the cuckoo. They will eat caterpillars the latter part of June and the beginning of July.

Perhaps your readers may be interested by a few more facts regarding this bird. It is somewhat remarkable that the egg should be so small compared to its size, when the nightjar lays an egg more than twice the size. The only birds I ever knew to rear a young cuckoo are the wagtail, hedge-sparrow, and titlark. It is also a fact that the cuckoo will suck the eggs of the hedge-parrow and deposit its own egg in the nest; and where more eggs are laid in the nest afterwards and the young ones hatched they remain till the cuckoo gets about half grown, then it ejects its companions and they perish. The old birds having to work very hard to supply the cuckoo with sufficient food, which

it devours with greediness, and so quick does it open its mouth, and so wide, that the old birds are soon minus of feathers on the top of their heads, and about the time it is fledged and left to seek its own food the old birds appear completely scalped, having the appearance as if the skin was off to the skull. This I have witnessed both in the titlark and hedge-sparrow, although I never saw it in the wagtail. I once saw a cuckoo alight on a heap of flint-stones which were for building purposes. I drove it away, and in about ten minutes it turned again, and alighted on the same spot. I watched for a short time, then drove it away. Being at work close by, I again saw it come to the same place. I then went to the spot, but could not see anything that could induce the bird to come frequently to one place. I then approached as near the heap of stones as I could, and hid myself behind a bank where I could observe the movements of the bird should it return again. In about a quarter of an hour it came, and again alighted, and tried to get in amongst the stones. I then went and removed some of the stones, and to my great surprise, about 18 inches beneath I found a wagtail's nest with four eggs. Had I seen either of the wagtails about the stones I might have been almost certain they had a nest here. Now, whether that cuckoo wanted to deposit its own egg, or suck the eggs of the wagtail, I could never ascertain, as the aperture that admitted the wagtails would not admit the cuckoo. *William Jacob, Naturalist, &c., The Museum, Sadler's Row, Fetterworth.*

PRUNING CONIFERÆ.—The impression is no less common than true that the management of woods in this country is either very imperfectly understood or badly executed. It is, however, of little practical importance which is the case so long as the fact remains that a great evil exists somewhere, either in the knowledge or practice of forestry; and should I be fortunate to any extent in either preventing the further extension of the evil or showing how it is produced, that others may guard against it, I will do at least something for my country's weal and the people's good.

As respects diseased trees, and even mismanaged woods, prevention is everything—cure next to nothing. Nature, it is true, performs her own work unerringly, and so far as natural productions are required, she does unaided all that is needed or desirable better far than by the assistance of art. In the culture of forest trees, however, which are produced for purposes of art and industry, rather than as natural objects, the aid of art is called in to direct, or it may be to subvert, the ordinary course of Nature. As, however, wide and different opinions prevail, both among theorists and practical men, as to how much and what part art should be called upon to perform in the culture of forest trees, or how far Nature should be allowed to take her own course undisturbed, it becomes the more necessary to point out carefully the various results of the different modes of pruning the various species of Coniferæ, and leave those specially interested to judge for themselves which course to adopt or which to avoid.

Between forty and fifty years have now elapsed since pruning Conifers was first practised in this country—if not upon a gigaotic style, at least in a sufficiently varied and extensive manner to allow those who wish instruction upon the subject to learn and judge for themselves as to results. The pruning referred to as performed about forty years ago was done by or under direction of the late Mr. Gavin Cree, nurseryman, Biggar, and extended to all parts of the United Kingdom. His system at that time met with very general acceptance, was adopted and recommended by some of the most intelligent landed proprietors of the day, and he thereby earned for himself no small share of fame. Mr. Cree's system, like most others, contained much that was commendable, but the little that was wrong in it was sufficient to neutralise the good, and disorder and derange the whole.

The following is a brief outline of the system practised by Mr. Cree, which it is very necessary to give before pointing out the results; but very few, it is presumed, will at all anticipate, even after listening to

the theory, what the practical results were and have been:—

"The common sap having extended over all the branches, mingles with the fluid absorbed by the leaves, and losing the watery and acriform principles which are useless for nutrition, by evaporation, it returns down the vessels of the bark, and in its course deposits cambium, which forms the annual rings of wood, then extends to and strengthens the extremities of the roots, whereby they are made to extract more nourishment from the soil throughout the season; and as the two saps commingle in the leaves, the descending sap, which has not been deposited in like manner, mixes with that extracted by the rootlets, and is again carried up with the ascending sap.

"How to economise these fluids for the advantage of the tree is to be considered. It is obvious, then, that when the upper lateral branches are shortened to half the length of the leading stem, and the others proportionally, the sap has less superficies to cover than when they are allowed to extend to an improper length and thickness; in consequence there is a greater supply for every part of the tree.

"The branches which are shortened always remain slender, by reason of the small superficies of the branch, and the rapidity with which the sap moves; very little is retained by the branch, and, of course, nearly the whole is deposited in the body of the tree. This truth, with the fact that the foliage remains nearly a month longer on the trees so shortened than on others, accounts for the wonderful rapidity of growth effected by this method of pruning. The smallness of the branches is of advantage likewise, when it is necessary to prune close to the stem, as the wound made by that operation is proportionally small, and may be expected to cicatrise in the course of three years.

"It may be worth remarking that, if the branches are properly shortened, trees never become what is termed hide-bound. Even mismanaged trees, on which a dryness of bark has occurred, may be brought to a proper condition in the course of three seasons. In cases of this kind, the distance from the body at which the branches are amputated must be regulated by the size of the tree; the larger the tree the greater the distance.

"It has been found experimentally that trees under 18 feet in height and 15 inches in circumference advance, taken averagely, as much both in height and circumference in six years, if the branches are properly shortened, as they do in fifteen if these are not shortened, or are improperly pruned. The more trees are pruned close up to the stem before they are 18 feet high, this is proportionally retarded. Trees pruned close to the stem, when the circumference at the part is under 15 inches, take in damp, so that the tree, if dissected after a certain period at the part where the branches have been cut, will be found black into the pith. This department of pruning, when improperly managed, is the principal cause of rot, more particularly in the Larch. The reason is, the wood in young trees is more open in texture than in older ones."

Having already exceeded all due limits, I must conclude, with the intention of resuming the subject in my next paper. *C. Y. Michie, Cullen House, Cullen, N.B.*

Garden Operations.

PLANT HOUSES.

GREENHOUSE PLANTS.—In gardening matters those who look the furthest ahead in providing for the time to come, can invariably secure the best supply. This particularly applies to the propagation and growth of soft-wooded plants, which act as the filliog-in for conservatory and greenhouse decoration amongst subjects of a more enduring character, such as Camellias, Azaleas, and similar hard-wooded things. One great advantage in a sufficient supply of soft-wooded plants that are raised annually from seeds or cuttings, and discarded after flowering, to be replaced by others of a similar description, is that there need be no hesitation to stand them when in flower in situations where plants of a more valuable, lasting nature would be injured. This is especially the case at the present day, when the interiors of conservatories are arranged with a view to much better effect than they used to be when high stages were in fashion. These latter, no doubt, had the advantage in getting the plants up near the glass, but from their unsightly appearance they have given way to low stands, and in many cases dispensing with stands altogether by simply arranging the plants on the floors; but even in houses that are the best constructed, and stand in a position to receive a maximum of light, it will be obvious that the plants, from being further away from the glass, occupy a less advantageous position; consequently it becomes more than ever necessary to provide plenty of such things as are of a medium size to occupy the front positions in the arranged groups whilst in flower that from their nature

of only being grown for a single year, there can be no hesitation in using even in dark situations. The same may be said also of the quantities of plants that are now required for halls, staircases, and similar positions where comparatively little light reaches them. No doubt many of the harder-leaved more persistent foliage plants are the mainstay for this kind of work, yet a sufficiency of flowering subjects to intermix with them should always be at hand. For such purposes as the above during the spring months there is nothing more suitable from their bright cheerful appearance when in flower than herbaceous Calceolarias, if well-grown, so as to enable them to develop the dense heads of flower they are capable of bearing. If, as advised at the latter part of summer, two sowings of these were made, they will furnish a succession in bloom for many weeks, but, to make them of real use, they must be well managed from the time the seed vegetates all on through the winter. The first sowing, after being pricked out of the seed-pan into pots, will by this time be sufficiently large for potting singly, as, if allowed to remain too long, the roots become interlaced, and cannot be separated without breakage. They should have very rich, moderately open soil, consisting of four parts loam to two of leaf-mould and rotten manure sifted, with a good sprinkling of sand added. Three-inch pots will be large enough for the present, keeping them near the glass, and in a temperature of 40°, or a few degrees over, through the winter, always having a good look-out that they are free from aphides. The later-sown plants may yet remain for some time in the pots or pans in which they were first pricked out. The double rows of Petunias, from their naturally compact habit of growth, answer well to use similarly. Cuttings struck early in the autumn should now have a shift, keeping them stopped and near the glass during the winter. With a view to using in the same way, the later sowings of Cinerarias should now be moved into 6-inch or 7-inch pots. If the plants are well treated, these are large enough. The soil should be quite as rich as that recommended for Calceolarias. The earliest plants of these that have got their pots well filled with roots, and are now about throwing up their flower-stems, will be benefited by weak manure-water regularly, keeping them near the glass, and standing on a moist bottom, which is necessary to preserve their large lower leaves intact. Hydrangeas struck in small pots at the latter part of summer should, when these get filled with roots, be moved into others 6 inches in diameter, and kept in an ordinary greenhouse temperature. Mignonette sown for flowering in spring, if not already in the pots in which it is to bloom, should be at once moved into them. Where the plants are forward and large it is necessary to give enough room-room to keep the foliage of a green, healthy colour, without which, even if fairly flowered, they have an uninviting look. Callas, where grown in sufficient quantity, may be easily had in flower six months during the year; those planted out in spring in the open ground, and that have been taken up and potted, such portion of the stock as intended for the later spring blooming should be kept quite cool, anywhere away from frost will do where they will get sufficient light, with enough water to keep the leaves fresh. Kalosantes propagated from cuttings twelve months ago should be kept as near the glass as possible. Upon this a great deal depends their flowering. Give just enough water to keep the soil slightly moist, but not too wet. See that no aphides are lurking in the points of the shoots, as they frequently take up their habitation here during the winter, doing serious injury before they are detected. Dipping in tobacco-water is the best remedy when these plants are affected. Any one who provides a sufficient quantity of all the above-mentioned subjects, so as to give a continuous supply through the spring and early summer months, will not be at a loss for flowering plants for conservatory and greenhouse decoration. Chrysanthemums.—Although, as I have previously remarked, there can be no greater mistake than to take Chrysanthemums indoors too early, or before their flowers have begun to show colour, yet they are so unusually late this season that the time has now come when it is not safe to let them remain out longer, unless where there is some means of protecting them. If there happens to be an unoccupiedinery, where the leaves by this time will be off, there can be no better place for them, as here they will get sufficient light and can have abundance of air. Keep on giving them a regular supply of manure-water; if any of the latest have not had their buds enough thinned let this be attended to. *T. Baines.*

FRUIT HOUSES.

STRAWBERRIES IN POTS.—The rainfall which we get at this season of the year dispenses in a great measure with watering these plants by hand. At times, however, the opposite conditions prevail, and render it necessary that this matter must be attended to as heretofore, because Strawberry plants luxuriate best with an abundant supply of water at the roots, providing it does not by any means become of a stagnant nature. If the weather continues favourable

for vegetation, these plants will continue growing for a considerable time yet, and they may with advantage still remain outdoors until much more severe weather approaches, when they should be removed to their winter quarters until they are required for forcing. When the plants are in a state of rest, in our opinion, they should be kept cool and not in an arid state of atmosphere, and therefore we advocate the use of cold frames and pits as being superior places for them under such circumstances. If these conveniences are insufficient for the purpose, turf pits are readily made, which will answer the same purpose. We plunge the pots in either coal-ashes or spent tan, to prevent the action of frost breaking the pots, and to keep moisture at the roots of them at less cost in time in watering, and cover with lights, shutters, or tarpauling cloths only, when absolutely necessary from stress of very severe weather. At other times fully expose the plants to natural influences. As the first batch of these plants when they are started will be benefited by having a slight degree of heat at the roots, timely attention should be directed towards the means of providing it, a fermenting bed being most suitable. *George T. Miles, Wycombe Abbey.*

VINES.—In low-lying damp situations, where the natural soil is cold, heavy, and unfavourable to the culture of the Vine, the management of the roots is of the greatest importance, as Grapes cannot be expected to finish or keep well, neither can the wood be properly ripened, if they are allowed to range over an unlimited space beyond the control of the cultivator. Where these conditions have to be met, and borders are unsatisfactory, no time should be lost in setting matters right. The bottoms of the borders should be concreted, with ample drainage for the free passage of water when supplied in large quantities through the growing season, and if, after the first six feet of compost has been placed for starting the Vines in, the remainder is added in small quantities annually, a great number of active roots will permeate every portion of the soil, the heavy expense of making new borders all at once will be avoided, and the piecemeal system will keep the Vines much longer in a satisfactory state, as the roots will have a constant supply of fresh food which will keep them within the influence of solar heat and moisture. When Vines in these situations have filled the allotted space, instead of allowing the roots full range of the surrounding soil, a portion of the border should be forked over, all strong roots shortened back and relaid in new compost made up of rough turfy loam, old mortar, also rough crushed bones, and a liberal supply of earth or garden refuse, burnt or charred with wood. On light soils where the roots can be allowed to find their way into the vegetable quarters without fear of injury or shanking, the addition of heavy loam and well rotted spit or cowdung will form a good substitute for the burnt earth or potash. The extension system should also be followed, as Vines with a number of rods frequently produce excellent Grapes where single canes are short-lived and a comparative failure. Up to the present time the weather has been all that can be desired for ripening of late fruit and wood, and having been able to give abundance of air with a moderate supply of fire-heat the Grapes promise to keep well. If not already done the latest houses may now be divested of all latent growths and laterals down to the main buds, but the old leaves should be carefully preserved and allowed to ripen off by a gradual reduction of heat and moisture. Prune successional houses and carry out the usual routine of cleansing and painting in order that the wounds may have time to heal before fire-heat is applied. Remnants of crops hanging in autumn houses which are required for plants may be cut and taken into the Grape-room, were they will keep as well as if left hanging on the Vines. *W. Coleman.*

CUCUMBERS.—By this time plants raised for taking the place of the late Melons will be fit for turning out, but if the latter are not ready for removal the Cucumbers should be shifted into the fruiting pots, and kept near the glass in another compartment, before they become pot-bound. At this place the latest crop of Melons is grown over the path of a Pine stove, and, as the Cucumbers have to cover 6 feet of trellis over the north bed before they reach the Melons, we can have the latter quite as late in the season as they are worth eating. Rollison's Telegraph is still one of the best winter Cucumbers either for private use or market, and having an excellent constitution it is less liable to canker than more delicate kinds. Look over bearing plants at least twice a week, and keep them sufficiently thin of vine and foliage to allow a free admission of light. Remove all male blossoms as they appear, and regard heavy cropping as one of the greatest evils that can attend the culture of winter Cucumbers. As days decrease in length less water at the roots will be required, but anything like drought or starvation must be avoided if red-spider is to be kept in check. An occasional syringing during the continuance of this bright autumnal weather will be found necessary and beneficial, the evaporating troughs may also be kept filled; but when the change

comes moisture must be used with greater caution, and an occasional dusting with flowers of sulphur must be the remedy employed for keeping red-spider in check. Use rough turf and old mortar for earthing, little and often, as the roots appear upon the surface. Water with tepid manure, in sufficient quantity to moisten every particle of the soil when necessary, but avoid the use of solid manure, either in the compost or on the surface of the beds, as it only encourages worms. The pots should be partially plunged in a bottom-heat of 90°, and, if the top-heat is allowed to range from 68° by night to 80° or 85° by day, a few degrees more or less will do no harm, provided the bottom-heat is kept steady. Maintain a sweet atmosphere by perfect cleanliness, frequent washing of the glass, and ventilation on all favourable occasions. *W. Coleman.*

KITCHEN GARDEN.

The end of the fruit-gathering season will throw more hands at liberty for the necessary work of preparation of the soil for future crops; this of course will include the trenching-up of all vacant plots of ground from which the crops have been removed. There is often more leisure at this season to perform the operation in a thorough manner, and it is advisable that the workmen be instructed to take plenty of room, say 3 feet wide trenches at the least, and after throwing out 2 feet in depth break the bottom well up and take care they don't have a ridge of solid, unbroken earth between each trench. The surface should be left as rough as the condition of the soil will allow, so that frosts may penetrate and fertilise it. I have a high opinion of the fertilising influence of severe frosts, but to obtain the greatest amount of good from it, it is necessary to take a little trouble to expose fresh surfaces as often as possible by deeply forking over in dry weather. Rough and half decomposed manure may be incorporated with the soil during the process of trenching, but for some crops it is preferable to use well rotted manure, which should be spread over the surface and left for some time, and when the rankness has been washed into the earth it may be said to be sweetened and should be at once pricked in and will be found in proper condition for the roots of crops to take hold of it at once. The ground intended for Carrots next year will be very much benefited by being subjected to the above routine of culture. Where new beds of Horse Radish are required the ground should be deeply trenched and a liberal supply of manure put into the bottom of each trench; 1 foot in thickness is not too much if fine roots are desired. If in this case the manure is incorporated with the soil the result will be that the roots instead of coming up straight will ramify in all directions in search of it. Asparagus beds should now be cleared of the stalks, and the weeds (which are almost sure to accumulate in such positions, where it is not easy to get at them with the hoe) should be cleared off; the beds may then be lightly pricked over, and a liberal dressing of rich manure spread over the whole surface of the beds and spaces between; this may lie until March, by which time it will be thoroughly sweetened, and will only need to be lightly turned over. The advent of frost, although not at present severe enough to be very dangerous to standing crops, reminds us to be on the look-out for what may soon follow. Amongst other things, the beds of Cauliflowers, Walcheren Broccoli, and Veitch's Self-protecting Autumn Cauliflower, will need to be frequently gone over, and such as are ready for use and not immediately required should be lifted and stored in an upright position in any outhouse or other available space secure from frost; the remainder should be often examined, and when advancing into flower several of the top leaves should be broken over the tops, which will greatly tend to preserve the young heads from the effects of our ordinary autumn frosts; if any do get frozen they must not by any means be allowed to thaw in the sun. The Lettices and Endive intended for storing should not be left too long in the open ground at this season; a few slight frosts, such as we experience in early autumn, will not be of any great consequence, but if the frost is at all severe it causes decay in the outer foliage, and, considering that we are never safe after this time, it is best to be beforehand with the weather and get the crop stored at once when in a suitable condition. The earthing-up of the main crops of Celery should now be brought to a close, and it would be well to have some kind of dry protecting material, such as dried Pea haulm or light litter from the stables, stored, for the purpose of throwing over the ridges in severe frost; this covering should always be kept on during the bright sunny days which often succeed frosty nights, but should be removed in mild dull weather. Now is a good time to sow as many lights as may be required of red and white Turnip Radishes in frames; spent hotbeds will answer exceedingly well, but, if these cannot be spared, 2 or 3 feet of prepared stable manure will produce sufficient gentle heat on which to sow, but it will require very free ventilation for some time in fine weather, and a little air on at night as long as moisture arises. *John Cox, Kalleaf.*

THE
Gardeners' Chronicle.

SATURDAY, OCTOBER 27, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Oct. 29	Sale of Dutch Bulbs, at Stevens' Rooms. Sale of Stock, at the Milford Nurseries. Godalming, by Protheroe & Morris (five days).
TUESDAY,	Oct. 30	
WEDNESDAY,	Oct. 31	Sale of Mr. S. Ralli's Collection of Plants, at Clapham Park, by Stevens. Sale of Stock at the Stanhope Nursery, Westerham Hill, Cudham, Kent, by Baxter, Payne & Co. Sale of Roses, Fruit Trees, Shrubs, and Dutch Bulbs, at Stevens' Rooms. Meeting of the Linnean Society, at 8 P.M. Sale of Dutch Bulbs, at Stevens' Rooms.
THURSDAY,	Nov. 1	
SATURDAY,	Nov. 3	Sale of Stock, &c., at the Moulsham Nurseries, Chelmsford, by Protheroe & Morris. Sale of Camellias, Azaleas, Palms, and Dutch Bulbs, at Stevens' Rooms.

FULL of years, rich in the esteem of his fellows, with the happy consciousness of duty fulfilled and work well done, THOMAS RIVERS has, in his eightieth year, bowed his venerable head, and succumbed to the fate which overtakes one and all the race. In another column we have endeavoured to indicate some of his achievements as a horticulturist, and to chronicle some of those results of his zeal and skill which have caused him to be looked on as one of the greatest horticulturists of this or any former age.

We need not tell the tale twice over, but to give point to our remarks let us recall for a moment just a few things which we owe wholly, or in the main, to RIVERS. True, in many cases he but revived old practices or adopted them from the French, but in reintroducing he extended and improved them. We allude to root-pruning and lifting of fruit trees (1839), double grafting, orchard-houses (1851), cordon training, ground vineries, the introduction of the Manetti stock, constant experiments towards the cheap and efficient construction of houses for fruit culture, and in the cross-breeding and selection of fruits and other plants. His experiments, moreover, were carried on with true scientific method, and recorded with something like scientific accuracy, on which account, as well as for the interesting results obtained, he must ever hold a high place among vegetable physiologists. Results such as RIVERS obtained have rightly secured for him the admiration due to successful enterprise and the gratitude which is the right of those who supply the needs, add to the comforts, and enhance the luxuries of their fellows. RIVERS, though a keen business man, was no mere commercial horticulturist pursuing his art for mercenary ends only. He was an enthusiast. He was guided as much by a love of truth and a desire to seek it where it might be found, as for the sake of any personal advantage to himself.

He had the courage of a pioneer, the zeal of an explorer. Actuated by the sacred fire of real genius, he pursued his end fearlessly, looking neither to the right nor to the left. A calmer, more cautious man would have taken a wider survey than did RIVERS, but it is very questionable whether he would have advanced his art to so great a degree as he did. At the same time this habit of looking at one side of a question too exclusively not unfrequently led him into controversy, and as a controversialist he acted on the principle "*à la guerre comme à la guerre.*" We are not imputing this to him as a subject for blame, but merely as an illustration of the workings of his mind. A less energetic or a more cautious man would have accepted a compromise—would have tried to look upon a question from his opponent's point of view, would have made allowances for circumstances; but this is not what RIVERS did. Confident in the possession of a clear head and brilliant energy—trusting, and with reason, to the wealth of knowledge he had made his own by acute

observation and hardly-won experience—he encountered his adversary with a degree of heedlessness which to onlookers suggested apprehension that, in the long run, the victory might not be wholly on his side.

This impetuosity of attack was the more noticeable when directed against any form of presumption, charlatanism or deceit, or anything which he considered to savour of those qualities. Here his love of truth welded to his enthusiasm roused his wrath, and sore indeed were those who, under such circumstances, fell under his merciless lash. The true nobility of his nature, however, showed itself by the way in which he allowed by-gones to be by-gones. The lapse of time suffered him to see and appreciate the fact that those who had opposed him had done so from motives as honourable as his own. Then ensued a degree of respect, in some cases a friendship, as marked as the former antagonism. His portrait, a votive offering from some of those who admired the man and respected his achievements, was presented to the Trustees of the Lindley Library, and hangs in the Council-room of the Royal Horticultural Society. As a likeness it is admirable. Long may it remain, to remind those who were his contemporaries of one of the greatest of their Fellows, and to stimulate those who come after to the achievement of work such as has made the name of RIVERS a household word among the horticulturists of the whole world.

WITH this issue we present our readers with a coloured plate, designed and executed by Mr. WORTHINGTON SMITH, and representing the common MUSHROOM, together with some of those suspicious allies most likely to be mistaken for it. The description of these plants will be found at P. 519.

— We are glad to hear of the safe return from Western America of Sir JOSEPH HOOKER, after an unusually long and stormy passage across the Atlantic. Sir JOSEPH brings with him large collections of plants from the Colorado and the Rocky Mountains of the North-Western States.

— An unusually EARLY FALL OF THE LEAF this year is reminding us forcibly of the near approach of winter. It is probable that this last stage of autumn has been accelerated more by other causes than by the most natural one—the season. The long and unusual drought that has prevailed is lending powerful aid in stripping the trees of their leafage. The terrible storm of wind that prevailed on the night of the 14th inst. did its part also, as the trees in exposed places were half-stripped of their leaves; and, not least, the successive sharp white frosts of last week have caused the foliage to fall in perfect showers. Probably few gardeners will lament this early disleafing, as the fall is at all times productive of an abundance of work and worry, and keeping a place tidy is for the time out of the question. Generally we have had the November gales and the fall of the leaf in unison, making for the time a sort of worms' paradise; this year, when the inevitable storms come, we shall probably have most of the leaves safely stored, and then the worms will find themselves deprived of their customary occupation. As usual, the Elm holds to its foliage with the greatest tenacity, and thus shows its great value as a decorative tree. The Hawthorn hedges, where exposed to the fury of the late storm, have their few remaining leaves browned and seared as with fire. Large-leaved trees, such as the Chestnut, Ash, and Sycamore, have shed their foliage specially early, and will have a long season of rest, unless the early fall should be productive of an early spring leafage. In southern districts, where the want of rain has been most felt, the rich tints of autumn leafage have soon disappeared, thus robbing the landscape of some of its most pleasing effects. Farther north, where the summer has been marked by an excess of rain, a dry autumn would tend to prolong the beauties of the trees, but in the South the contrary effect has resulted. Doubtless most gardeners will echo the wish that, now the fall has begun, the sooner it is over the better.

— NEW VEGETABLES—that is to say, new kinds, not new varieties of old kinds—have as a rule a poor chance, as we most of us prefer cultivating what we know to be good and palatable to troubling ourselves with a novelty of doubtful quality. This is in some respects a pity, because there are probably many wild plants which, by cultivation and careful selection, would give birth in a few generations to superior varieties, and add to our choice of vegetables. What has been done with such undoubted native plants as Carrot, Parsnip, Celery, and Seakale, is a proof of what, with perseverance, can be effected in this way. Then there is the Cabbage and Turoip tribe, which, if not actually indigenous in Britain, are natives of neighbouring countries. Indeed, if we leave the Potato out of consideration, we are indebted to the New World to a very small extent. Our native flora and that of the Mediterranean region conjointly stock the fruit and vegetable garden. From time to time somebody brings forward a new vegetable, which is received in a half-hearted, sceptical manner, barely tried, and then rejected. Because we have already a very good choice of vegetables, that is no reason why we should be content, and not trouble ourselves to add to the number. Any one having the time and means might find some interesting employment in experiments on untried plants likely to prove useful in this way. Recently a French gardener sent a substitute for Spinach in summer to the committee of the Central Horticultural Society for an opinion as to its merits. There is great difficulty in growing Spinach in some parts of France in hot dry summers, and in some soils it is quite impossible. The plant proposed to replace it is quite an old acquaintance, being the "Ice Plant," *Mesembryanthemum crystallinum*. This plant was familiar to all the members of the committee in its ornamental aspect, but not one of them could say anything of its value as a vegetable; consequently it was decided to give it a practical trial. The verdict was favourable. It is said to have very much the flavour of New Zealand Spinach, and like that requires cooking at least twice as long as ordinary Spinach, and in a large quantity of water, otherwise it has a strong, somewhat acrid taste. Properly cooked, it is said to be equal to common Spinach, and it can be grown at a season and in a soil unsuited to the latter.

— Messrs. SUTTON & SONS announce that their twenty-eighth ANNUAL ROOT SHOW will be held at Reading on Saturday, November 24.

— The young tender green FRUITS OF MARTYNIA LUTEA are said to flourish an agreeable pickle in vinegar, treated in the same way as Gherkins. We learn from the *Journal de la Société Centrale d'Horticulture de France* that it is being tried by some of the members, but no particulars of its quality are given. Another plant under trial is a kind of Cress, a species of *Senebiera* from the Pampas of Buenos Ayres.

— The PARSNIP CHERVIL, *Cherophyllum bulbosum*, remains almost unknown in this country, whereas our French neighbours are taking some pains to improve it. Samples have been frequently exhibited in Paris this season, and one grower, M. CHOUVET, received a certificate for some roots of unusually fine quality. They grew in a peaty soil which had been manured the previous year, and they received no other care beyond hoeing. Roots grown in this way are fit for use at once, whilst the roots of plants in highly manured ground, or watered with liquid manure, are not good to eat for two or three months after lifting. The seed was sown in February and the roots dug in the middle of August. When the seed was sown it had already sprouted about a quarter of an inch, having been stored in layers of sand. This is a necessary precaution to preserve the vitality of the seed until sowing time.

— In a span-roofed house belonging to J. LIMMER, Esq., of Woodside, Ipswich, may be seen such a show of GRAPES as would astonish any one unacquainted with the capabilities of well-fed Vines. The house referred to contains thirty-six rods, principally Black Hamburgs, on which were recently to be seen upwards of 800 bunches that would at the lowest estimate average 1 lb. each. The berries, although not over large, were as perfectly coloured and finished as Grapes could well be. The Vines are in their fifth year, so that they have not arrived at their full strength yet, and as the house is not heated it

shows what good use has been made of the sun to have the fruit ripe, and the wood in a fine nutty brown condition, betokening maturity, and giving promise of a fine crop next season. In a lean-to house planted last spring twelvemonth some splendid rods have been formed that measure quite an inch through, and have huge thick leaves with stout massive footstalks and buds so large, full, and plump that they now look ready to burst. Mr. LATTEK, Mr. LIMMER's enthusiastic gardener, attributes much of his success to the large quantity of sewage he uses, of which, situated on a hill as this vinery is, on a loose gravelly bottom, they will take any quantity. Mr. LIMMER, with a wise forethought for this, has had a large tank made to catch all the drainage from the house, which is thus stored up for the use of his garden instead of being wasted, as is the case in most places. There can be no question that were gardens better supplied with liquid manure, and a free use made of it, much better results would be achieved than is now possible in such dry seasons as we have had for years past. Loose gritty porous soil induces fibrous roots, and, with so many feeders, all it wants to bring good crops of whatever kind is plenty of sewage, not given in dribbles, but in sufficient quantity to thoroughly soak it through.

— We hear that Mr. TAYLOR, who has been gardener and general manager at Isel Hall, Cocker-mouth, for the last five years, is leaving that situation at Christmas, in consequence of the Hon. P. T. WYNDHAM, M.P., having given up his residence in Cumberland.

— One of the most beautiful varieties of DELPHINIUM in cultivation at the present time is one named BELLA DONNA. It has a neat and compact perpetual-blooming habit, and lovely azure-blue flowers, with a white centre. We saw it at Mr. PARKER's nursery during the summer months, planted alternately with dwarf plants of *Acer Negundo* variegatum, and the combination was a very striking one. Another of the very best is *Delphinium magnificum*, a perpetual bloomer, with flowers of a rich blue colour suffused with bronzy red, and a white and orange centre. Add to these two the distinct and beautiful double lavender-blue flowered *D. Keteleeri*, and we have a trio of perfect gems. To make half-a-dozen we should add to the above Madame E. Geny, reddish purple, tipped with blue, and blue and white centre; Coronet, dark blue, with purple and orange centre; and Gloire de St. Mande, a fine double variety, of a brilliant blue colour, shaded with crimson on the edges of the petals.

— Dr. PEYRITSCH, it is reported in the *Botanische Zeitung*, has been attempting to fix peloria and abnormally irregular flowers by selection and propagation from seeds. The total result of the experiment was that no essential difference existed between the seed, which would produce the peloria and normal flowers. With one lot of seed from pelorial flowers of *Leonurus cardiaca* all the offspring produced terminal pelorial flowers; but in another experiment there were more cases of peloria from the seed of irregular flowers than from the seed of pelorial flowers. And about half of the pelorial seedlings reverted to the normal form.

— Dr. KRAUS recently read a paper before the Natural History Society of Halle on the DISPERSION AND SIGNIFICATION OF WATER IN THE PROCESSES OF GROWTH AND TENSION IN PLANTS. Some of the results of his researches are briefly stated in the *Botanische Zeitung*, from which we borrow them. If a normal, vertical shoot exposed to light equally on all sides be halved by axile section, the amount of water in the two halves is equal, but a curved shoot lying on the ground, divided horizontally into an upper and a lower half, will always yield a larger quantity of water in the lower half. This unequal dispersion of the water may be detected a few hours after the shoot has been laid down. It also occurs in rigid woody stems. In normally (perpendicularly) growing radicles the distribution of water is the same as in the stems. A bent radicle contains more water in the upper half than in the lower. A germinating root, 3 or 4 centimetres long, laid horizontally there will be some hours before it begins to bend, an unequal dispersion of the water in favour of the upper side. From experiments conducted last winter it was ascertained that the bark contains more

water during the night than in the daytime. With this increase of water there is a greater shortening and a radial expansion; that is to say, the nocturnal diameter of the trunks of our trees is greater than the diurnal. This radial enlargement of the trunk by night is entirely due to the swelling of the bark; not the least change in the diameter of the wood can be detected. This may be proved by putting fresh rings of bark into water, as they will shorten to a measurable extent, and thicken at the same time, whereas wood treated in the same manner undergoes no appreciable alteration. The nightly swelling of the bark is caused by water from the wood, and warmth effects the transfer of the water. The daily diminution of water in the bark is the result of transpiration.

— That charming Iridaceous plant, *CYPELLA HERBERTI*, is not generally known to be hardy, but so it has proved with Mr. PARKER, and the fact is worth recording, for it is a wonderfully floriferous plant, continues in bloom for about three months in summer, and its showy orange-yellow flowers are exceedingly attractive. It is not a new plant, having been introduced from Buenos Ayres some fifty or sixty years ago; but it is not so frequently met with as it deserves to be.

— Perhaps few Conifers display more striking variations amongst its offspring than the graceful *Cupressus Lawsoniana*, numberless forms of which, all differing in some particular from the normal type, may be met with where Conifers are grown. To these may now be added a very distinct variety which Mr. PARKER will soon put in the trade, and which, on account of its close, compact, bushy habit of growth, he has well named *densa*. In addition to its sturdy habit, the foliage is tinged with grey; and, taken altogether, it may be put down as a good thing.

— Mr. GUILFOYLE's report for 1877 on the MELBOURNE BOTANIC GARDENS contains some interesting items of information. The best grasses for forming a good turf have been found to be *Stenotaphrum glabrum*, Buffalo-grass, *Cynodon Dactylon*, and English lawn grasses. Three serious nuisances are occasionally experienced in the gardens, in the shape of rabbits, wild cats, and dogs. The rabbits are very numerous and mischievous; and the cats are very destructive to the small birds, particularly the English thrushes, but the latter are fortunately getting rather numerous in the gardens. *Eucalyptus ficifolia*, which was only known to Mr. BENTHAM by imperfect specimens in fruit, is described as the grandest of its tribe. It has the beautiful foliage of *E. calophylla*, and scarlet blossoms of a most gorgeous character. Three large summer-houses have been erected in different parts of the grounds for the accommodation of the visitors, each one having seat room for fifty persons. Respecting the Mesquit Bean, *Prosopis pubescens*, a curious letter, written to Mr. DYER by Mr. R. THOMSON, superintendent of the Botanic Garden in Jamaica, is printed in this report. By way of experiment Mr. THOMSON gave about a pound of the pods to a fine healthy horse, and three days afterwards the horse was found lying dead "in such a position that left no reasonable doubt that it had died from belly ache." The letter concluded with the statement that this belly ache is attributed to the germination of the seeds in the stomach of the animal! If true, this might be avoided by cooking the Beans before giving them to animals. Although it is a dangerous food, the Mesquit Bean is said to be a valuable fodder, as well as the seeds of an allied species, *P. juliflora*. A band has performed a selection of music, in favourable weather, on alternate Saturdays throughout the past year; and one large moonlight concert was given. The conduct of the people was excellent on these occasions, not the least damage having been done. On the other hand, it is asserted that everything is being done to render the establishment worthy of the name of a botanic garden.

— A correspondent has lately favoured us with a MULTIPLE GRAPE, consisting of several berries run together so as to form one large lobulate berry. Such berries are not uncommon at the end of the bunches. We presume that in the early stages of growth the elongation of the branch bearing the berries does not keep pace with the increase of the berries themselves, and hence the berries become fused together. Its occurrence at a later period might possibly be pre-

vented by timely thinning, though we suspect the union takes place at too early a period to be prevented by thinning.

— One of the most beautiful tints of colour to be found amongst flowers is a brilliant orange-scarlet, and when associated with beauty of form, as in *PAPAVER ALPINUM MINIATUM*, a neat-habited and continuous-blooming plant of great beauty, nothing, to our thinking, can excel the combination in loveliness.

— Dr. GRISEBACH has contributed a report to the *Geographische Jahrbuch* for 1877 on the PROGRESS OF GEOGRAPHICAL BOTANY, which is a useful summary of recent contributions to this branch of botany by travellers in various parts of the world. Most of it is pretty well known in this country, but some notes on the forests of Russian Lapland, from the work of H. and K. AUBEL, are interesting. The polar limit of trees was ascertained at the following points. Below Kola in 69° N. lat., about the middle of the course of the Ponoï in 67°, running southward to 66° 20' on the south-east coast. On the opposite peninsula of Kanin the tree limit forms a similar curve, starting from the Arctic circle on the west coast it reaches 67° 40' in the west of Petschora. The large forests of Russian Lapland consist, according to the estimates of the travellers named, of one-half of Pine (*Pinus sylvestris*), one-third of Fir (*P. Abies* var. *obovata*), one-sixteenth of Larch (*P. Larix* var. *sibirica*), the remainder divided among a few other trees, the principal of which is the Birch. The most northerly forests in Kola consist of Pine, which are on an average not more than a foot thick, and heavily laden with Usneas. The Firs on this tree limit attain scarcely a height of 20 feet. The largest Pines measured, and which, according to the number of rings, were from ninety to one hundred years old, were 40 feet high, and the trunk 18 to 21 inches in diameter. Many trees attain only about half these dimensions in sixty or seventy years, and then perish. This premature dying off of undeveloped trees proceeds from the interior outwards, and from the apex downwards, and is accompanied by an excretion of resin. The trunks of Birch and Aspen also decay early. Other trees observed in high latitudes were *Pinus Picta*, northwards to 64° in the Government of Olonez; *P. Cembra*, in the district of Mesen, in 58°; *P. Larix* var. *sibirica*, in the same locality and on the Pinega, an affluent of the Dwina, up to 64°.

— In the last volume of the *Linnaea* to hand is the commencement of a sketch of the VEGETATION OF PORTUGAL by Dr. E. GOEZE, who spent ten years in the country. This part is wholly devoted to the climate, geology, and physical geography of Portugal. The flora of Portugal is in certain regions the richest in Europe, and much remains to be done in thoroughly exploring it. GOEZE's sketch will be welcome and useful to any one going on a botanical trip, and we may give the principal features of it in a condensed form, when the whole has appeared.

— To lovers of choice alpine plants we commend one of the most beautiful of all, and a valuable addition to the genus *OMPHALODES*, *O. Luciliae*, which we found in Mr. PARKER's nursery. It is quite new, has a low creeping habit of growth, with peculiarly pleasing silvery glaucous leaves, and pretty porcelain-blue flowers. It continues in bloom for a considerable time, and is altogether a gem of the first water.

— In *ANDROSACE SARMENTOSA* Mr. PARKER has a splendid new rock plant, which has not yet been sent out. It has a nice tufted habit of growth, and produces dense heads of bright blue flowers in early spring.

— It is said that COFFEE IS AN ANTIDOTE TO STRYCHNINE. Dr. ATTILIO LELLI having met with a case in which a dose of strychnia was administered in coffee without fatal consequences, was, as we learn from the *Lancet*, led to institute some experiments to determine whether it possessed antitoxic power against this drug. The animals employed were rabbits, and by comparative trials he found that a dose of five centigrammes proved fatal in a short space of time; when the same or a larger dose was given in a very strong infusion of coffee, he found that the coffee either acted as a complete antidote in preventing the poisonous effects of the strychnia, or that it materially diminished the violence of its action.

— The *Bulletin* of the French Society for Acclimatisation contains an interesting article by M. DE QUATREFAGES, on the PEOPLES OF THE ISLANDS OF POLYNESIA (understood here as including New Zealand and the Sandwich Islands, and, indeed, all the islands within a triangle formed by these two groups and Easter Island), and the part man has played there in bringing about the present distribution of plants and animals. The area over which these islands are scattered is nearly three times as large as Europe, and some of these islands and groups of islands are very distant from their nearest neighbours. Thus the Sandwich Islands are 1960 miles from the nearest group, New Zealand 1100, and Easter Island 840 miles distant from the nearest land. It is now placed beyond doubt that these islands were peopled by the same race. COOK proved that the language of the inhabitants of New Zealand, Tahiti, and other points was identical; and subsequent travellers have actually succeeded in tracing by means of traditional history the course of emigration. Some twenty years ago Sir GEORGE GREY translated a number of the historical chants of the Maoris of New Zealand. As near as can be computed it was early in the fifteenth century when New Zealand was colonised by emigrants from Rarotonga, the history of which has been handed down from generation to generation, even to the enumeration of many of the plants and animals they took with them. The Sweet Potato, *Batatas edulis*, and the Taro, *Caladium esculentum*, were among the plants introduced by the early inhabitants; but the Cocoa-nut and Bread-fruit tree, which are spread all over the tropical islands, would not succeed in the higher latitude of New Zealand. But M. DE QUATREFAGES mentions that the kernels of the fruit of the Karaka tree were among the articles with which one of these early expeditions to New Zealand was furnished. At the present time the endemic *Corynocarpus laevigata* bears that name, according to HOOKER'S *Handbook of the Flora of New Zealand*; but it is quite possible that the same name may have been applied to a different tree or trees. According to tradition, one of the first cares of the emigrants on landing was to plant the roots and seeds they had brought with them. Now there is as much difficulty in determining the native country of the Bread-fruit tree and Cocoa-nut Palm, as there is of our Grape Vine, cereals, &c. It is not so difficult, however, to say whether a plant is indigenous or not, as for instance of the Taro and Sweet Potato in New Zealand. Since the intrusion of Europeans in New Zealand, Tahiti, and the Sandwich Islands, the useful plants, according to climate, of nearly all parts of the world have been introduced, and, to a great extent accidentally, a vast number of weeds. In New Zealand upwards of 200 British plants are more or less naturalised, and some of them have unfortunately spread with amazing rapidity and become a scourge to those who cultivate the land. It is also recorded in the *Transactions* of the New Zealand Institute that the vegetation of the vicinity of some of the large settlements is more European than indigenous in character.

— It may not be generally known that the fine double-flowered PELARGONIUM DR. MASTERS, now in course of distribution by Mr. B. S. WILLIAMS, originated as a double sport from the old Fire King, at the nursery of Mr. JOHN REEVES, at Acton. As these free-flowering Pelargoniums are much grown for their flowers the double varieties are receiving much notice, and Mr. REEVES informs us that the double flowers command in the market double the price fetched by the single varieties. To market growers, therefore, the new double forms commend themselves on commercial grounds. For cutting from during autumn and winter the old Red Gannet is one of the best. Two and three year old plants cut back hard, root and branch, and repotted in August in 48 and 32-sized pots, are now throwing up their flowers, and will continue to do so till Easter. The bright rosy red blossoms are very acceptable at mid-winter, and the gay hues of flowers appear to be much more appreciable during the dull dead season of the year than when there is so much of life and beauty in outdoor gardens.

— The Pelargonium-house at Chiswick well repays inspection just now, for the choicer varieties of the Zonal section are in full bloom, and some of them are remarkably fine. It is interesting to notice what rich hues of colour the pink-flowering varieties take on at

this late period of the year, deepening to very pleasing tints of rosy magenta. One of the most striking is Dr. DENNY'S Rose of Allendale, and some of Mr. PEARSON'S pink varieties are charming in the extreme. Among white varieties Jeanne d'Arc promises to take a high place; the habit is good, the flowers of fine form and freely produced, and in all probability it will displace Madame Vaucher for market work.

— The finest form of variegated ABUTILON is undoubtedly DARWINII TESSELLATUM. Mr. BARRON has a capital specimen of it at Chiswick just now, the large bold leaves of a well-grown plant being most handsomely marked, and, indeed, it is not too much to state that there are distinct shades of colouring in the variegation, the deep green of the leaves being marbled and blotched with golden yellow and pale yellow. In addition the flowers are freely produced from the leaf axils, and their distinct colouring is in marked contrast to the variegation seen in the leaves. It will make a showy plant for conservatory decoration during winter, for then it appears to shine out in its gayest character.

— The cultivation of DOUBLE TUBEROSES for their flowers in this country is a remarkable branch of horticultural enterprise. A large number of Tuberoses are annually imported for this purpose from France, and some clue may be obtained to the quantity when it is stated that Mr. JOHN REEVES, florist, Acton, imports 30,000 annually; but then he has flowers almost all the year round—last year with an intermission of six weeks only, this year he hopes to have an unbroken supply "all the year round." The first batch is potted singly in large 60-pots about Christmas and earlier, and there are successional pottings till May, fresh batches being introduced as required. The bulbs potted at Christmas and onwards are started into growth in a brisk bottom-heat, and shifted into a 48-pot as soon as required, when they have grown to a height of 12 inches or so, and then pushed on into bloom. The later potted roots are put into a cold house to flower after being gradually hardened off. The bulbs potted in May are placed in a cold frame, and during summer fully exposed to the elements; by September some of them are throwing up their flower-spikes, and as they continue to do this introduced into heat to expand their flowers. There can now be seen in Mr. REEVES' nursery a considerable number of plants in bloom, and still in the open air a very large number coming into flower. The Tuberoses appear to do well in any light soil, and there is no professional secret of this character in the cultural process. At this time of the year the spikes carry five and six and more of the richly fragrant flowers, but as the days shorten and the fogs abound the latter cause the topmost buds to decay, and Mr. REEVES states that in the depth of winter one or two flowers only will be perfected. It has been asked will the Tuberoses flower in the open ground round London? It might do so if grown on in pots and turned out early in summer as soon as warm enough to do so, but if planted in the open ground it is more than doubtful if the flower would be produced early enough to escape the damp and cold of autumn.

— A telegram from Paris states that the Phylloxera has appeared at Plantières, near Metz, in German Lorraine.

— Mr. BARRON has worked up a good stock of Colonel TREVOR CLARKE'S new hybrid BEGONIA MOONLIGHT, at the Chiswick Gardens, and nice bushy plants of it in the propagating house are laden with their large white flowers. It is most appropriately named, for there is a kind of lustre shed from the stout alabaster-white flowers. It promises to be as useful in every respect as the well known \times B. weltoniensis.

— Messrs. CARTER & Co.'s ROYAL METROPOLITAN ROOT SHOW is announced to be held at the Agricultural Hall, Islington, on November 14 and 15.

— The progress of the seasons has again brought us to the time of the year when CULTIVATORS OF THE TULIP are turning their attention to the preparation and planting of their beds. This also includes examination of the bulbs, a preliminary step of some importance. They should also be arranged ready for planting, at the same time making good all alterations

in position noted at the blooming season, and at this time of year such new varieties as will enrich a collection may also be obtained. An important matter is the preparation of the bed. If the soil has been in use only one year, and the Tulips did well in it, it seems scarcely necessary to change it; for if the soil be good the bulbs may be planted in it two or three years in succession provided it be properly tilled and enriched. The rule observed by many cultivators is to remove about 3 inches of soil from the surface, laying it in ridges by the sides of the bed; then to fork over the mould left in the bed, laying that also in a high ridge for a week or ten days. If the soil requires changing growers take about 10 inches in depth of the soil and replace it with sand, decayed turf, good loam and road-grit, mixed well together. This is forked over two or three times, and laid up in a high ridge till planting time. Those who live in manufacturing districts need to be careful in selecting their loam, as in 1876 Mr. SAMUEL BARLOW, of Chadderton, nearly lost a good number of his best varieties by using soil from a hedgerow that had become impregnated with iron. In planting it is customary to place a little sand about the base of each bulb, and a little sulphur is also added by some cultivators; the soil is then put carefully back on the bulbs, and it is covered to a depth of 4½ inches in the centre or highest part of the bed, and 3 inches at the side. Tulips are generally planted seven bulbs in a row, and their position in the row is regulated by the height at which they grow. The time for planting varies in different districts; in the North it is sometimes done as early as the second or third week in October, in the South Lord Mayor's Day, November 9, was the generally observed day for planting. The condition of the bulbs is some indication of the precise time, as, for instance, when they begin to show signs of activity at the point, and by the swelling of the incipient roots at the base of the bulb. Sufficient space should elapse between the renovation of the bed and the time for planting to admit of the soil subsiding to its level. Generally, as soon as planting is finished, the iron hoops used for protection are placed over the bed, ready to place Frigi-Domo mats, or any other suitable covering, over it when the state of the weather makes it necessary.

— ROGIERA GRATISSIMA is a plant much used at Floors Castle, and Mr. KNIGHT, writing in the *Florist and Pomologist*, says he finds it of great service all the year over. "By adopting a system of potting and stopping, it may be had in flower all the season, but it is essentially a winter-flowering plant. It gives great returns for the trouble it takes in growing, more so than most ligneous evergreen plants do. Its bunch of flowers is not unlike a fine Carnation, but with more pink in it, and being sweet-scented it is most grateful in a nosegay. For those fan-shaped nosegays which are now becoming so fashionable, I don't know of a plant better adapted for them. I once fringed a Court bouquet with about twenty trusses of its flowers, which had a most beautiful novel effect. We have plants from 7 feet high down to 6 inches, half of which are, more or less, in flower. One plant 5 feet high has upwards of seventy flowers open and opening. A standard with a 2 feet head is being pinched in order to get it in flower in October, with others smaller, and a large planted-out plant. I fancy the plant is not sufficiently well known, or it would be more grown than it is. It is of simple culture, and does admirably in an Azalea-house, though it does not require heat to grow in. We grow it in soft fibry loam, with a dash of burnt ashes through it, and in this it thrives vigorously. We use a nice warmth to our Azaleas in spring, and this extra heat suits them well, and it bears more heat if you want it to flower earlier in winter—say December. I rank this plant as certainly equal, and in some respects superior, to *Luculia gratissima*, as it is a better habit, in being more comeatable, and the leaves can be used in nosegays with their flowers, and it can be had in flower at all seasons. I got my stock from LINDEN, who sent it out some years ago, and I have not regretted keeping to my old love, which from the first I pronounced a real gem. Whoever takes it in hand will, I am sure, thank me for bringing it to their notice, and more especially those who must have choice flowers to the fore for nosegays, &c. I am not too sanguine in saying that were I a florist, and wanted a speciality, this certainly would be either first, second, or third on my list of pets."

ARTISTIC GARDENING.

As there are gardens and gardeners, so there are gardeners and gardeners, gardening and gardening. Between the forecourt of a suburban cottage and the grounds of princely Chatsworth, between the poor "froz-n-out" day labourer and the master of the art of horticulture, there exists a difference as great and marked as between the various styles of gardening. We have passed through many phases of the art more or less distinguished by certain peculiarities, we have had the useful as well as the ornamental, the ornamental and the useful combined; we have had the severely simple and the highly ornate, the architectural and the natural, and, finally—that is to say at the present time—we may be said to have the artistic. How far the present fashion in horticulture deserves the appellation we will presently discover, but here, let it be fully understood, our remarks are not meant to apply to extensive gardens held under the charge of professors of the art of horticulture: the artistic gardening, or rather the style which appears to lay claim to the title, is that displayed in the small area of villa gardens, the floral arrangements of town houses, &c.

First as to the meaning of artistic. In the sense in which it is applied to horticulture it is surely meant to imply the elevating of the occupation of the gardener into an art, into work on which the labourer shall bring to bear all the resources of knowledge at his command, the evidence of such knowledge to be displayed in the laying-out and planting of grounds in the most pleasing and suitable manner; so that, considering the whole, we shall find uniformity without sameness, diversity without heterogeneity, each part being not only good and beautiful in itself, but dovetailing into the whole so as to heighten the general effect. In fact artistic gardening should consist in bringing to bear upon the subject all the fruits of experience, study, and observation possible, so that in the outcome of knowledge, in the practical evidence in the garden itself, or in the numerous minor portions of it, such as window, balcony, or *jardinière*, there shall be nothing incongruous, nothing to shock the most fastidious taste, nothing which brings heterogeneous subjects into a proximity which detracts from the beauty of all. On looking around the metropolis and observing what goes on about us we cannot but be struck by the universal diffusion of a love of flowers as evidenced by the general efforts to grow them somewhere and somehow. With this widely awakened taste for beauty has arisen a development of decorative garden accessories which are employed without thought, and therefore without fitness. Such are the window-boxes of virgin cork displayed on stuccoed houses. Is it possible to find anything more incongruous than the flat imitation stone surface, the severe pillared porticoes, the handsome expensive plate-glass windows, with an adornment of rustic beauty? It is a misplacement of beauty which jars upon the senses in a manner similar to that which might be felt were we to behold the picture of some village belle taken from the picturesque yet ordinary surroundings of her daily life, and placed in a modern drawing-room: the face and figure of the rustic beauty framed in an environment of woods and fields and the accessories of country life would appear to the best advantage, while such a figure as the principal attraction of a *salon* would be out of place and absurd—a fit subject for satire, a theme for ridicule; the charm of face and figure would be utterly lost from the incongruity of the surroundings, as the rugged form of rustic window-boxes is when placed on modern imitation Italian architecture.

This is but one of the many phases in which artistic gardening belies its name: it is to be found all around us, in greater or less degree. At one time its most glaring form was the painting of railings, garden seats, arbours, any indeed of the adjuncts of the pleasure-ground, a deep uniform green colour; this fashion happily is dying out, we have learnt from the French to employ a deep red-brown tint as the most suitable to be used for wood and iron work in gardens. It were well we should only go thus far, not copying our neighbours in the profuse amount of gilding employed by them, nor following the too prevalent fashion of making garden pavilions of such a form and of so many hues that they have the appearance of abortive attempts at Eastern pagodas and miniature minarets.

To return to English gardening. Although we do not see the improprieties of little mounds, little pavilions, little fountains, and little grottos in a space

some few yards square—all of which are so commonly found around the *maisonette* at Auteuil, Passy, or other village outskirts of Paris—yet in many instances the laying out of and planting of a small garden is as inartistic here as it is in France. There space is frittered away, and by attempting too much all is lost; here the reverse is generally the case. Given a villa garden enclosed within brick walls, how seldom is any attempt made at masking the ungardensque character of the fence, or, by judicious planting of suitable subjects, depriving the enclosure of the hard outline of a formal square? As a rule, three narrow, level borders follow the line of wall, the fourth side of the square being formed by the dwelling-house; four straight paths and a square of lawn complete the laying-out of the villa garden; the summer planting follows the fashion of the day, and carpet-beds and ribbon-borders give to the ground the glory of brilliant colouring for a few weeks. Another form of laying-out is that where life-size statues and gigantic tazas stand obtrusively out on lilliputian lawns and diminutive terraces, or, interspersed amid attenuated shrubs, only add to the general *outré* appearance and dreariness of the whole. Gleaming white [More frequently dirty. Eds.] statuary beneath the sunny skies and amid the dense Myrtle groves of Italy, in conjunction with the classic architecture and æsthetic memories of the country, is appropriate and therefore beautiful; but such statuary, smoke-begrimed and out of place within the walls of the limited area of a suburban villa garden, is inappropriate and ridiculous.

Since a part of the Horticultural Gardens at South Kensington was first laid out with coloured sands this style of what we may term imitation gardening has become a rage with some people, and we have seen villa gardens in which during winter the beds have been laid down with broken stones and chemical refuse in geometric patterns. Such gardens always remind us of the miniature grounds laid out by the children on the seashore, which are planted with cut flowers; such child's play has, indeed, more of the true ring of a love of Nature and plants about it than the idiosyncrasy which delights in parterres of coloured stones. A sincere horticulturist would find more real pleasure in cultivating the veriest wayside weed than in laying-out such gardens, which at the best are not so interesting as the well-designed pattern and artistically blended tints of a parlour carpet. T. S. F.

THE EXTENSION OF FRUIT CULTURE IN AMERICA.*

As the source of light and heat travels from the East, completing its daily circuit on our Western shore, there to rejoice in all his strength, so fruit culture has crossed our continent to the Pacific slope, there to produce almost all the fruits of the habitable globe, and finally to permeate, enrich and adorn our whole land.

At the time of the organisation of our Society the cultivation of fruits for market, or for exportation, was limited to a few of the older States. In Mr. Coxe's opinion the fine Apple growing section was bounded by the Mohawk River in the North, and the James River in the South. Fruit growing in this section was confined principally to Apples and Peaches, but very few of the latter found their way to the markets of the North, while Strawberries and other small fruits were scarcely to be seen, except in the locality where they were raised.

But now almost every steamer from New York for Liverpool or London, in the fall and winter months, takes Apples varying from 500 to 3000 barrels. Shipments have been made from other ports, and as late as last May there were 1500 barrels sent to England from Philadelphia. In December last 90,000 barrels of American Apples were landed in Liverpool. Very little difficulty is experienced in the winter months, but arrangements have been made to ship in warm weather by vessels with refrigerator compartments.

As the refrigerating process becomes more and more perfect it will aid largely the exportation, not only of Apples, but of more delicate fruits. Pears, Peaches and Grapes have been sent to England in good order, and it is confidently expected that American Peaches will soon be well known in the markets of England.

But what shall we say of Canada, Iowa, Wisconsin, Minnesota, Kansas, Nebraska, California, Oregon, and other sections, and other new States and Territories, where the cultivation of fruits had scarcely

* From President Wilder's address, delivered at the sixteenth session of the American Pomological Society.

commenced when this Society was established? Who that witnessed the exhibitions of fruit from the States first mentioned at our various sessions in Richmond, Boston, Chicago, and at the Centennial in Philadelphia, has not been surprised at the progress already made?

At the time this Society was formed the area of fruit culture and the value of our fruits was so limited that it was not thought worth while to collect the statistics. Then many States, Canada and Nova Scotia, had given but little attention to fruit culture, except that of Apples. These and other sections were deemed too far north for successful fruit cultivation. Now they produce large quantities of fine fruits: the Nova Scotia Society have received four medals from the Royal Horticultural Society of London, and the Ontario Society, at the Quarter Centennial Session in Boston, in 1873, the Wilder Medal for the best collection.

The estimate by the Government for the Centennial, last year, furnished the following statistics (soon to be published), of the fruit culture of our country:—

The number of acres under cultivation, in orchards, Vines, and small fruits, is estimated at 4,500,000. The number of trees is estimated as follows:—Apples, 112,000,000; Pears, 28,260,000; Peaches, 112,270,000; Grapes, 141,260,000; the total, 393,790,000. The estimated value of fruit products is:—Apples, 40,400,000 dols.; Pears, 14,130,000 dols.; Peaches, 56,135,000 dols.; Grapes, 2,118,900 dols.; Strawberries, 5,000,000 dols.; other fruits, 10,432,800 dols.; making a grand total of 138,216,700 dols., or nearly equal to one-half of the value of our average Wheat crop. California, to say nothing of Figs, Oranges, Olives, and Almonds, has nearly one-third of the whole Grape area, 60,000 acres of vineyards, and 43,000,000 of Vines, yielding annually, besides Grapes and Raisins for the market, 10,000,000 gallons of wines, to which may be added the wines of Missouri, Ohio, and other States, the whole wine product being 15,000,000 gallons as the annual crop.

The following are a few illustrations of the immense quantities of fruits which are sent to market in addition to what is consumed at home:—

Of Strawberries there were received in one day in the New York market, at the height of the season, from all sources, 7000 crates, averaging at least a bushel and a half each—more than 10,000 bushels. The crop of Peaches raised in this country is so enormous that we hardly dare state the quantity. The largest crop was in 1875, and on the peninsula of Delaware and Maryland alone was estimated at between 7,000,000 and 8,000,000 baskets.

From California, according to the statement furnished me by Mr. E. J. Hoopes, Editor of the *California Horticulturist*, there were sent East, in 1876, 334 carloads of fruit, of 400 bushels each—an increase of more than 100 per cent. over the previous year, one firm having sent 700 tons; and of the Strawberry it is estimated that from San Jose and vicinity, some days there were sent for home consumption forty tons of this fruit, and in a circuit of about five miles there are more than 1000 acres of this fruit under cultivation. Dr. Strentzel, our Chairman of the Fruit Committee for California, writes, that at short notice that State can furnish the whole continent with an overflowing supply of fruit.

From Virginia, Mr. Leighton, our Vice-President, writes, that the increase of Strawberry culture in the vicinity of Norfolk is astonishing, completely heading the page of horticultural progress, and that it seems wonderful how the demand keeps pace so closely with the supply. The shipments this year have been over 3,000,000 quarts. There were nearly 10,000 pickers in the field in one day. One grower had 185 acres. To Boston alone there have been shipped this year 11,547 crates of 45 quarts each, or more than 16,000 bushels.

In Illinois very little fruit was raised, except for home use, until 1840, when, according to Mr. Flagg's interesting historical address before the State Horticultural Society, a new era in fruit culture commenced. Now there are 320,000 acres of orchards in that State. Mr. Parker Earle informs me that in a good season there have been sent from his station alone (Cobden) twenty-five carloads of fruit daily. Of Strawberries, where scarcely any were raised sixteen years ago for exportation, within six or seven years the cultivation has increased, at Cobden and vicinity, to over 1000 acres, so that five or six carloads daily are dispatched to the various markets.

From Georgia, Mr. Berckmans, President of the State Horticultural Society, writes as follows of the late exhibition of his society:—

"Many of our people of intelligence were amazed at our progress. The exhibition of fruit was grand. I am safe in saying that the display of Peaches was never surpassed, if equalled, in any place in the past. I had fifty-six varieties of Peaches, all ripe and in perfection; others had collections almost equal in number, and several surpassing in size. Many had Peaches measuring 12½ inches in circumference. The Grape show was almost equal to the Peach exhibit. Upwards of fifty varieties were exhibited. Some wonderfully fine Concords were shown, which weighed 1 lb. to the bunch. Pears were fine, but not numerous as to varieties." He had forty varieties in eating condition, which, together with the balance of his collection, made nearly 200 varieties of fruit.

The increase in the crops of Apples in New York, Michigan, and the more Western States, is wonderful.

From New York it is estimated that in abundant years 1,500,000 barrels are exported, in addition to those consumed at home—a single firm at Boston receiving from that State from 30,000 to 40,000 barrels of Apples per year. In the best seasons, Monroe, Niagara and Orleans counties produce more than 1,000,000 barrels of Apples, and the value in one county is stated to be a million of dollars.

Michigan is a great fruit producing State, and many parts of it fully up to New York. The crop of Apples in this State is estimated by Vice-President Lyon at 2,000,000 dols. in value; Peaches, 1,000,000 dols.; and other fruits 1,000,000 dols., or a total of 4,000,000 dols.

Home Correspondence.

The Late Potato Show at the Aquarium.—As you intimate your approval of the letter of "A. B." [In principle, not in all its details. Eds.], I think it proper to direct your attention to matters of fact. The promoters of the International Potato Exhibition made an earnest endeavour to locate their exhibition at South Kensington, and failed to obtain from the Council of the Royal Horticultural Society any definite reply to a very definite proposal. The endeavour proved injurious to the Potato show, for it delayed operations fully six weeks beyond the time when the arrangements should have been completed. But as you agree "in principle" with "A. B.," I must inform you that adjoining the conservatory at South Kensington is a drinking-bar, and on days of great exhibitions a second drinking-bar is opened at the lower end of the garden. It follows that alliance with the Royal Horticultural Society would continue and strengthen the present "unholy alliance" between "Potatoes and gin." But you, under the leadership of the apocryphal "A. B.," would, of course, soon surmount such difficulties. I therefore desire it to be understood that at the next meeting of the International Potato Exhibition Committee I shall propose that the whole arrangements for 1878 be entrusted to the unknown "A. B." and the Editors of the *Gardeners' Chronicle*. *Shirley Hibberd, Stoke Newington, N.* [Our correspondent may call spirits from the vasty deep, but—Eds.]

Your correspondent "A. B." is no doubt very smart in his criticisms upon "little societies" as he calls them, but will he please to explain how he is aware that the promoters of these little societies have no other object in view than their self-glorification, and that with them the advancement of horticulture is as nothing? I say distinctly such sneers as these are most contemptible, and are flung by some one who can show no success that he has accomplished. [A bad guess this. Eds.] Does any one whose opinion is worthy of consideration doubt that Mr. McKinlay, the chief promoter of the Potato show, has not in view the improved cultivation of the Potato, and is actuated by motives as honourable as is any man in England? Let the same be said of Messrs. Horner and Dodwell and the Auricula and Carnation Societies; of Messrs. Paul, Turner, Cant, Hole, Camm, D'Ombrian, and others that represent the Rose show. Are not these honourable men, and have just as much right to hold their exhibitions where they please as have the Council of the Royal Horticultural Society to set up their little shows at South Kensington? How is it that these men are only "Brown, Jones, and Robinson" in the estimation of "A. B.?" Are they not as good any day as the puffed-up *parvenus* of the Royal Horticultural Society? If the Royal Horticultural Society wants the support of these little bodies, why does not it try to secure their assistance in a liberal spirit? "A. B." cannot be aware that the Potato Committee endeavoured to obtain such terms from the Council of the Royal Horticultural Society in the spring as would enable them to

hold their show at South Kensington, but whilst the Council were parleying over the matter, an offer came in from the Aquarium Company of assistance to the amount of £30, while the Council of the Royal Horticultural Society offered only £10. Had the Council been but a trifle more liberal, the show would have been held at South Kensington. If, however, they are too illiberal towards the little societies to receive the support of the latter, rather let "A. B." blame the Council than these small but nevertheless useful bodies. "A. B.'s" horror of Westminster saloons and joint stock public-houses is ridiculously pharisaic; it is a gross slander upon the myriads of respectable people who frequent either of the places he condemns to say that they go there to drink gin. If "A. B." will take the trouble to go to the drinking bar at the end of the western arcade at South Kensington on any great show day, there he will see more bar-drinking going on than he will see on any show-day at either the Aquarium or at the Alexandra Palace. The quarrel of Potato Committeeman with the manager of the Royal Aquarium had nothing to do with the accommodation furnished with the number of visitors, of which there were twenty times as many as would have got to South Kensington—not with the drinking business. I have as keen an eye for the evils of that feature as have most men, and I fearlessly say, as far as the Aquarium is concerned, that I see less of it there than in many other places. My object in publicly complaining of the manager's conduct was to put other committees on their guard. With this exception only I have no fault to find with the Aquarium, or with the honourable way in which its engagements with others have been acted up to. *A Committeeman.*

Special Shows and Special Societies.—"A. B." confines his denunciation of special shows and societies to those only who do not go to the Horticultural. Speaking of those I am connected with, the fact is, that neither the Royal Horticultural nor the Royal Botanic Society would give us days on which either Auriculas or Carnations and Picotees could be produced; so that the severance was the work of the large societies, as they are generally called, and not our work at all. As to specialism and specialisms, what are Dr. Hogg, Worthington Smith, Andrew Murray, and every other man of mark in the present, as of the past, but specialisms? And, as for the specialists desiring isolation, I deny that any such feeling governs florists. They neither will submit to be left out in the cold, nor do they wish to leave aught out. As I have said before, we were shut out from the Horticultural Society and Regent's Park, and are, I fear, to be again shut out for 1878; but unless I greatly mistake florists, they will not suffer this in silence. *E. S. Dostwell.*

The Royal Horticultural Society and Small Societies.—Does not your correspondent "A. B." (p. 500) put the consequence in place of the cause, when he says that one reason why the Royal Horticultural Society does not succeed is that the votaries of particular plants do not support it? Committees representing particular plants look only to the interests of their objects in choosing the place of exhibition—the Royal Horticultural Society has been so long looked upon by many of the best horticulturists of the country as a South Kensington institution, supported mainly by Kensington funds, and kept up mainly for Kensington objects. When it becomes the recognised representative Society of the country, horticulturists, whatever their special hobby, will naturally support it, and make it their show place. The Society will get the support of the country when it shows that it fully merits it. One difficulty is that the funds which will result from the support are much wanted to help fully to earn it. "A. B." does not include the Crystal Palace among the "gin and beer" places; perhaps he has seen, as I have at the flower and fruit shows there, the many visitors with eager appreciative faces, such as I hope we shall one day have at South Kensington. *George F. Wilson.*

Notes on Flower Shows, &c.—The letters which have appeared lately in your columns about flower shows prolonged on Saturday nights will no doubt have their effect, still in getting up successful shows the main thing that has generally to be considered is how would early closing of shows on Saturdays suit the treasurer. It is just possible that flower shows held in London could be closed for the exhibitors sooner by an hour or two than shows held in the provinces. In London the visitors might be called more of the upper class, and therefore could attend earlier—I might say they do attend earlier; but in the country it might be said in most cases to be quite different. For country shows the large influx of the working class on the Saturday afternoon is just the very thing that makes the show a success, and the fact of the matter would be just like this—to close early on the Saturday afternoon would be to weaken the finances of the society. Taking home a few loads of big plants even a few miles late on

Saturday night, extending into Sunday morning, is quite as stiff a job as taking a box of fruit 100 miles now-a-days. Still it might be safely said that, whatever could be advanced about prolonging the shows on the Saturdays, it will resolve itself into this—will it pay to close earlier or not? There can be no doubt that flower shows that are not in a right way financially soon lose patronage, and early closing would not do much for them were they to adopt the principle without due consideration to all other points. Whilst I would be in favour of every exhibitor getting home in reasonable time after the show, at the same time I would caution against early closing if it were to affect the standing of the society in paying its way. I believe there is another matter connected with flower shows that often gives more trouble than the late closing on Saturdays, and that is the making of awards that do not give satisfaction from the improper or indistinct wording of the prize schedule. Judging from what often appears in your journal about disputes or inquiries concerning rules for certain awards, &c., very few shows pass off without something of this sort; and perhaps though the schedule might have cost the society a great deal of care in its production, still in country shows I think this is a point that generally an improvement can be effected in. If means were adopted to reduce such unsatisfactory awards to a minimum it would be a step in the right direction. Such are the thoughts of *A Provincial.*

Three-Day Shows and Saturday Terminations.—I think the remarks which have already appeared of this journal in reference to the desirability of closing exhibitions of valuable perishable fruits before Saturday night will meet with the acquiescence and support of all exhibitors, and without going into details here I think sufficient evidence has already been given by practical supporters as to satisfy the promoters and managers of such undertakings that we, as exhibitors, have in this case an undeniable grievance to place before them, and one which ought to be amended. I trust, therefore, that before the ensuing season's arrangements are completed the arguments which have been adduced will have due consideration given to them at the council boards for forthcoming shows, and that for the future we shall be spared the inconvenience and additional expense incurred by the late arrangements. The question as to the duration of large shows is another matter, involving other interests of the first importance; the liberal prizes which were given by the managers of the Alexandra Palace show should, however, set this matter at rest in this case. *G. T. Miles, Wycombe Abbey.*

Shropshire and Cheshire Damsons.—In your current number for October 20, p. 497, you call attention to the goodness of the "Shropshire Damson." It would be very serviceable to know the regular trade name, if it exists, of this excellent variety, which I conjecture to be the same as the kinds much prized in the West of England as the Derbyshire and Cheshire Damson. The Derbyshire I only know by reputation, but the Cheshire kind when imported as far south as Gloucestershire is a remarkably free and constant bearer, with a good-sized oval fruit, ripening well, and pleasantly tasted even uncooked. The large yield makes it very valuable for winter supplies in any of the common forms of preservation, and it is especially useful as a cottage tree, from the fruit requiring no more trouble and expense than covering it in a deep jar with a good layer of brown sugar, and setting it in a boiler till the sugar has melted down amongst it, or setting the jar for a few hours for the same purpose in a spent brick oven. In Cheshire, this kind of Damson will keep for a while laid like Apples on straw in a loft, but in the warmer climate of Gloucestershire the fruit ripens thoroughly on the trees; they have also the advantage of caring (as far as I have seen) little for soil or situation—those I knew best standing in a stiff lias clay, and being much shaded by a you g Fir wood, and the wild-wood plants and grasses which grew over their roots being rarely meddled with beyond one rough mowing in the year just before the fall of the fruit, and with this I only remember a failure (an approach to one, rather, for there was some crop) once in a long series of years, and generally the trees were heavily laden. I have endeavoured to procure this variety near London, but have only met with the conjecture that it is the "preserving Damson," and I should be very glad to know if it has some name under which it is procurable. *O.*

The Worcester Pearmain Apple.—Excuse me if I differ from you about the Scarlet Pearmain called the Worcester. I send you by this post a bundle of descriptions made by me here two or three years ago from specimens of the various sorts of Apple in my collection. I send you the bundle, as you will find that I am not without proof that the Pearmain called Scarlet Worcester is in my opinion nothing else than the one described by me as Pearmain Scarlet Summer, which you will see coincides with the fruits I send

you. I have since examined leaves from the Worcester sort and from Scarlet Summer, and I find them alike; and I must say that there is no test better than the venation of leaves. You will find also a description of Scarlet Winter Pearmain, which ripens from December to April, whilst the summer sort ripens exactly at the time claimed for the Worcester. I do not wish to hinder the raising of new fruits, but I should be pleased if the parties raising them would authenticate their parentage. *John Scott, Merriott, Crewkerne.*

Mrs. Pince's Black Muscat as a Stock.—My experience with Mrs. Pince is that it makes a very good and suitable stock to graft upon. I have one here that has been planted eight years in an inside border, and which the second year after planting produced a couple of bunches. From its not colouring up to my satisfaction I grafted a Black Hamburg upon it, and this Vine has proved superior in every point to others grown in the same house. It still retains the two lower spurs which every year carry a bunch each, never colouring up to the mark sufficient for extending which is its failing point with the majority of growers. *W. B., Oct. 23.*

New French Roses.—A correspondent asks a question in last week's *Gardeners' Chronicle* about a certain indefinite 144 of these Roses of the issues of the past five years. From the way in which the inquiry is put it is almost impossible to give a categorical answer, unless "S. X." supplies the names of the lost ones, whose merits, demerits, or fate he desires to know. It may be pretty safely enunciated, however, at once, that all or nearly all that he refers to may be justly referred to the condemned list of mediocrities and failures with which so many of the Gallic raisers try the patience of English rosarians year after year. There is an important point in relation to these French novelties, of late years too often left out of sight. Now-a-days they do not all come here. Warned by that stern teacher, experience, our importers refrain from that prodigal disbursement for all and every individual of the untried and unknown in which they were wont to indulge, and confine their investments to the productions only of those who have proved themselves worthy of confidence. Hence the English catalogues do not coincide in all cases with the French lists of novelties. Another reason which tends to restrict importations from the foreign market is the increasing number of English raised Roses brought before the home public, the means of testing the qualities of which are more complete. Perhaps "S. X.'s" interest in the missing kinds he appears anxious about may be somewhat abated or satisfied by the sweeping assertion, as some might consider it, that from four to five kinds every year exhaust the really distinct and first-class French Roses that come out. "S. X." therefore, need not wonder that 144 should be left out, but rather that so many are retained. However, if he refers to any particular Rose or Roses I will give him whatever information can be obtained. *W. D. Prior.*

— It seems to be a fact that, if what appears in your issue of the 13th and 20th inst. is true, during the last five years there have been imported from France into this country not less than 234 inferior varieties of Roses, and these have been heralded into the English market with high recommendations, and are, as far as words go, prodigal in beauty. It appears, however, that all the buyer gets for his money is this fine description, which in the end is dissipated by the alloy of bitter disappointment. The annual influx of new French Roses is at hand, and considering the results of former years there surely ought to be written up on every list as it arrives "*caveat emptor.*" The sum of money paid to the Frenchmen for these so-called new and improved Roses is more than any one unacquainted with the matter would imagine; but as the money is paid by dribbles, it may be surmised that the buyers look upon the matter with the contempt which familiarity is said to engender. The cost of these new Roses is, including carriage, as nearly as may be 25s. each, so that, supposing only twenty plants of each of these 234 sorts have found buyers in England, it represents a sum total of about £5800 paid to the French Rose-growers during the last five years, and for this amount there is nothing to show except the names in some catalogues, from which they will soon be struck out. I am informed it is invariably the practice with the English nurserymen to select the best stocks to bud, and the best ground upon which to grow the new Roses; this, together with disbudbing, insect killing, manuring, watering, and all other approved modes of promoting the growth of the plant, and the development of the bloom, are resorted to without stint; but the result must be very mortifying to these careful and energetic cultivators when they find that, after all this painstaking watchfulness and outlay, they can seldom find a bloom fit to show to a customer as a good new Rose. In former years the French Roses were generally good, excepting that now and then we had a counterfeiter, but as it came surrounded by a lot of genuine ones it did not attract much notice; now, matters

are quite reversed. I hope the decadence in these French Roses does not arise from the old and respectable growers dying out and their places being filled by others who are not so scrupulous or who have lost the art of raising good Roses; for without doubt some of the best new Roses we have had of late years have been raised in England. I think the Rose-growers of England ought to cordially thank you, Mr. Editor, for calling attention to this matter; and I trust your remarks will tend to augment and uphold the reputation which the English Rose-growers have always endeavoured to maintain. *Alpha.*

New Spotted Grape.—The enclosed Grapes and leaves were taken from a Vine grown from the seed, by Mr. Gill, of The Fernery, Lynton, North Devon. The Vine is now nearly ten years old, and has always shown the variegated peculiarity, which runs through the whole Vine. There are four Vines growing in the same house, but none of the others are marked at all. I merely mention this to show that the marks are not attributable to blight. The Vine is a large one, the bunches average about 2 lb. each, grown without heat. *Francis A. Stringer, Chancery Lane.* [We received a few weeks earlier a sample of the same Grape direct from Mr. Gill, and concluding that Mr.

FIG. 107.—SHOULDER FROM A CLUSTER OF MR. GILL'S SPOTTED GRAPE.

Gill's Fern-house, facing north, afforded no opportunity for bringing out the qualities of the Grape either as to size or ripeness, and that as a seedling its constantly spotted berries were a curiosity, we advised Mr. Gill to place some eyes in Mr. Barron's hands to be carefully grown at Chiswick; and this we learn he either has done or intends to do. In the meantime the annexed sketch (fig. 107) of one of the shoulders of the bunch will show the condition to which Mr. Gill has grown it. The spotting is a genuine coloration of the skin of the berries, and is developed in about equal degree throughout the bunch. It is not, as appears to have been suggested by some persons who had seen it a discoloration occasioned by blight or disease. *Eds.]*

The Best Cucumber.—A neighbour of mine who reads the *Gardeners' Chronicle* recently remarked to me, "I notice that some one has been writing about 'Telegraph' as the best Cucumber, but I prefer Blue Gown to that." He added, "I put out this last spring two plants each of Telegraph and Blue Gown in a pit. They both did well, and bore lots of fruit all through the summer, but Blue Gown held on, and was producing beautiful fruit 20 inches long at least a month after Telegraph had given out, yet both sorts were treated exactly the same." Further, he added, "In a frame Blue Gown does splendidly, and whilst it is of first-class flavour,

Telegraph can't touch it for colour." I have thought this impromptu opinion of a good gardener worthy of general publicity. *A. D.*

Galvanised Iron.—We notice in your issue of this week a query as to effect of "galvanised iron" upon Roses and Raspberries when trained to it. We beg to inform your correspondent that no form of vegetation will make much progress if attached to any metal whatever, simply from the fact of its great conducting power, which causes the metal to be cold and ungenial to all plants. Some few years ago a case came under our notice of a Hop grower experimenting on a small scale with iron rods in one of his "gardens," on account of the great saving there would be in their durability as against ordinary poles, which were continually rotting. The effect was that the Hops would not climb up them, but in preference crept upon the ground, and in all cases where they were tied to the poles to prevent this course, only a poor stunted growth ensued. We have never found Roses succeed well where they come in direct contact with metal out-of-doors. It would be well if some of your ingenious correspondents could discover some more durable material than wood which would answer as well in arches and trelliswork. Could not iron wire, insulated in gutta-percha, or some such non-conducting medium, be successfully adopted? *William Rollison & Sons.*

Eucharis amazonica as a Cool Greenhouse Plant.—Kindly allow me to endorse "D. T. F.'s" statement respecting the above plant. About seven weeks ago we took several pots of this charming and ever-acceptable plant, when in flower, and placed them in the triangular or inner hall in the Castle, where they were subjected to plenty of air, the doors being open on all favourable occasions. The first morning after being put there they showed symptoms of flagging, they having been taken from a close, warm stove, but after they had been there a couple of days the spikes became quite stiff, and otherwise everything that could be desired, and remained so until last Saturday, when we removed them to the stove again. Of course, the blooms were picked off as they faded. Well-grown plants of the *Eucharis amazonica*, with its beautiful white sweet-scented flowers towering above its green and luxuriant foliage, have indeed a very fine effect. *H. W. Ward.*

— I am very pleased to be able to bear testimony to the remarks of "D. T. F." on the hardness of this prince of winter-blooming plants. I have a dozen large plants which are kept in sets of four, and seldom it is I have not a supply of them in bloom. Three or four of these sweet-scented flowers, associated with good old *Epiphyllum truncatum* with stag's-head Pelargonium, makes a bouquet fit for an empress. *R. Gilbert.*

A Plea for a Neglected Tree.—The deciduous Cypress is seldom seen, I suppose because in unsuitable situations it perhaps may assume a stunted or scraggy style of growth. Where it flourishes, however, it is an object of much beauty, from its feathery foliage and the peculiar tender green which it retains throughout the summer. I have one of these trees about forty years old which I think no one could fail to admire. It is growing in a stiff but not a wet clay, high up on the side of a hill, where it is above the influence of the frosts so prevalent on the lower lying country. *P. P. C.*

Agaves in Jean Verschaffelt's Nursery.—The following is a list of Agaves that flowered in this nursery during the past summer (1877), viz.:—1. *Agave filifera elegans*, a fine variety, imported a few years ago from Mexico; a very compact plant, dwarf, with numerous short leaves, more abundantly thready (filamented) than in the usual species or varieties, each leaf broadly marked with pure white bands; about 1 foot high by 18 inches in diameter. The flower-stem is about 5 feet high, covered with seed-pods. 2. *Filifera*, a most noble specimen, about 40 inches in diameter; the flower-stems nearly 15 feet high, covered with hundreds of flowers, a great many of which have been fertilised, and bearing numerous seed-pods. 3. *Xalapensis*, a really fine plant, about 2 feet high by 3 feet in diameter; flower-stems 3½ feet high. This species seeds very freely, for every flower has become a seed-pod. It is one of the finest green-leaved specimens of the *Agave* tribe. 4. *Agave lophanta*, one of the very finest and most esteemed species, but not common in the trade. The specimen in question was perhaps the finest known in commerce. The flower-stem measures quite 20 feet, and it has continued in flower for ten weeks. This does not set so freely, but yet, owing to the immense quantity of flowers, a certain quantity of good seeds may be reasonably expected. 5. *Schidigera*, an imported plant, 18 inches high by 16 inches diameter; flower-stems 3 feet high; very few seed-pods. 6. *Xylinaantha*: a fine specimen of this species threw up flower-stems quite 7 feet high, and has now a great number of seed-pods. Beside the above Agaves two or

three imported plants (trunks) of the very rare *Dasy-lirion Hartwegianum* (true) have flowered during the past season, but none of them have seeded. Several rare species of *Agaves* in my collection may be expected to flower next year. *Jean N. Verschaffel, Ghent, Belgium, October 20.*

The Apple Crop of 1877.—We have not an extensive collection of Apples, but seeing in your issue of September 8 that information as to the varieties which have borne good crops this season would be acceptable, I may say that the following have done well here (in South Hants):—Dessert: Nanny Apple, Stone Pippin, King of Pippins, an exceedingly heavy crop, good size, and highly coloured. Kitchen: Norfolk Beauffin, good crop; Wellington (or Dumelew's Seedling), good crop, very fine fruit and excellent colour. The trees of the latter variety are large, the stems measuring 5 feet 6 inches in circumference at 6 feet from the ground. The situation is 280 feet above sea level, and the soil dry and gravelly. We have no Pears or Plums worth mention. The past month was very favourable for Apples to finish off, and we were fortunate enough to finish gathering all in by the 10th, or we should not have required the use of ladders, the gale on that day having swept over here with great force. *J. Batters, Gr., Chilworth Manor, Romsey, October 22.*

Protecting *Polyanthus* Flowers.—I fear that the Rev. C. W. Dod will not in the future save his *Polyanthus* flowers from destruction, if he does not protect his beds either by nets or by wire netting. The sparrows have so often tasted the forbidden fruit that they will not be denied, and nothing short of powder and shot will frighten these audacious birds. They associate so largely with man and domestic animals that nothing but destruction or prevention will keep them at bay. I find them productive of the same mischief with my African Marigold flowers in the autumn, and only netting will keep them off. What food they find in these flowers I have not yet been able to find out. *A. D.*

Potato Disease.—If your correspondent "R.," writing under the above heading, would try (instead of mowing down the stems) pulling them up by the roots, I think he would find that any tubers not affected at the time of pulling the stalks would keep quite sound. I have tried it several times. We walk along each row, putting one foot on each side of the stalk, grasp it with the hand, and pull it clean out. The Potatos served in this way have invariably turned out nearly free of disease. Perhaps some of your correspondents will try the above, and give their experience. Of course the stalks must be pulled out as soon as the disease shows itself. *W. A. Emery, Kilkenny Castle.*

Arundo Donax and the Pampas-grass.—At p. 500 a correspondent, "S. W.," recommends *Arundo Donax* to be planted near water and otherwise. He also recommends the Pampas-grass for the same purpose, but he forgets to say that both these plants perish if we have a severe winter. I have to cover mine every winter with a thick layer of coal ashes, to save the roots. Did any one ever see this fine grass in flower in Britain? Madeira is its native habitat. *John Scott, Merriott, Crewkerne.*

A Cure for Root-eating Grubs.—In January last you were kind enough to write to me in answer to my inquiry for a cure for the "grub" that was eating up my Strawberry plants. I tried "sulphur," recommended by a correspondent of the *Gardeners' Chronicle*, without any success, as we found the vermin alive and well in the middle of the sulphured earth. As you requested me to write to you on the subject, I have now much pleasure in recommending a perfect cure—viz., the copious application of quicklime—small doses are useless. I feared at first I had burned up my plants, but they recovered, and bore an abundant crop, and the grub seems annihilated. Messrs. Sutton & Sons, of Reading, suggested the remedy. *A. F.*

Eriopsis biloba.—I suppose that *Eriopsis biloba* is not an easy plant to grow; I have not often seen it in really good health. I have had two or three plants, which I bought as they were imported; they all grew vigorously, and one or two flowered, but I lost one or two of them, and have now only one, which appears to be very healthy and to be growing stronger and more vigorous every year. The pseudobulbs of this plant seem to be very slow in forming and maturing, and in the plant that died the leaves spotted and the bulbs shrivelled and rotted in the winter. The roots do not seem so liable to rot as those of many *Orchids*. The plant which is thriving is grown in a shallow cork basket, which it has filled with roots, hung up close to the glass in a Cattleya-house, and without having much water given it at any time. It certainly, as Mr. Williams says,

likes plenty of light; I should say that it likes to be warm and rather dry in the winter, and not too warm and moderately moist in the summer. *C. W. Strickland, Hildon, Malton.*

Anemone japonica alba.—Valuable as this *Anemone* is for beds and borders, it is doubly so for pot culture, for except in favourable autumns like the present it is very seldom that it lasts long in full beauty in the open, as the flowers are either cut off by frost or become so damaged by wind and wet as to disfigure them in such a manner as to quite spoil their beauty. I have found this to be the case just lately, owing to the strong gales; as on looking over a number of plants in the herbaceous border I could not find a single bloom but what had the edges so battered and bruised as to be unfit for the purpose required. Of course there are sheltered situations where this mischance may in a measure be guarded against, but not so from frost and wet or damp, foggy nights, which are equally fatal to their beauty, and therefore to enjoy them to the full it is necessary to grow some in pots, that they may be removed to the greenhouse on the approach of bad weather, where they will be found to display their peerless flowers long after those in the open border are destroyed or so tarnished and meagre as to bear no comparison with those under glass. Excepting the *Eucharis* there is nothing to compare with them for spotless purity, and were they as tender as that plant and required the same heat to grow them, they would no doubt be quite as much prized and sought after as is that popular favourite; but as they are only hardy herbaceous plants they do not receive the attention their merits deserve. Associated on the stage with red *Salvias* they form a most pleasing contrast, and last on till *Chrysanthemums* come in to take their place and fill up the void. The best way to manage them, to get them strong and to flower freely, is either to plant them out in rows in rich soil, and take them up just before they begin to show bloom, or to grow them in large pots, plunged and mulched; but the former method is the preferable one, on account of involving less labour, and being productive of more satisfactory results. The thing is to grow them freely, with plenty of leafage, which is sure to end in fine crowns that cannot fail to send up stout stems laden with bloom. If a shallow trench is cut similar to those prepared for *Celery*, and a good dressing of manure is dug in and then filled up, it will be just the place to grow them, and exactly suit their requirements, and to aid them as much as possible water should be given during dry weather, or, better still, liquid manure in lieu of it. When lifted from the ground it should be done carefully, so as to preserve as many roots as possible, and a fair-sized ball should be taken to minimise the check digging them up entails—an operation for which a dull, moist time is the most suitable, as then they suffer less and recover more quickly than when the atmosphere is hot and arid. A cold frame in a shady situation is the best place to stand them, as then they can be kept close and syringed till the leaves will bear full exposure without flagging, which they will soon do when so favourably circumstanced. *Anemone japonica* may easily be increased by taking the young offsets, which it established plants growing in favourable soils form freely around them, and should be removed in the spring, and planted in rich sandy loam; or seed sown at that time, and plants raised therefrom will flower the following year. One of the merits of *Anemone japonica* is that it lasts well in a cut state, and from its light branching habit is free from that stiffness that detracts much from the beauty of others. *S. W.*

Storm in Skye.—The following extract from a letter, received from my friend Mr. Anderson, of Carboth, Isle of Skye, may interest the readers of the *Gardeners' Chronicle*. *C. R. Haig, 118, Fenchurch Street:—*

"Last Sabbath (14th inst.) the barometer fell very low, and showed great signs of uneasiness. The wind commenced early in the morning to come in heavy squalls from the north-east, accompanied with rain, which by noon exceeded anything I ever saw in Skye. From that time to 3 P.M. it continued to get worse and worse, till it was no longer rain, but 'whole water.' The flood rolled down the mountains in one universal sheet, sweeping everything movable before it. Bridges were swept away as if they were pasteboard toys. The rivers spread out over their banks from side to side of the glens, and rivulets were swollen into rivers. The bridge at the end of my house, always more than sufficient for the largest flood I ever saw here, could not contain a tithe of the water. On rolled the mighty stream till there was not a bit of dry land round about the house. Stones larger than a man could carry, roots and trees, were swept over the lawn in front of our house into the sea as if they were feathers. My upper dam was swept away, and there were several feet of water in front of the distillery. By 4 o'clock the waters began to subside, and by half-past 5 one of the most desolate sights possible was presented to the eye. Thousands of tons of *débris* were lying everywhere. The road leading up the hill was washed away all its length to a depth in some places of 5 feet. The *débris* before the office door are still

several feet deep. By yesterday afternoon we succeeded in cutting pathways to admit of our getting along and to allow the water to drain off. Eels were found wriggling in my house on Sabbath evening. The house and distillery resisted the storm and flood, but the large bridge is swept away. To-day all hands are busy carting the *débris* away, but a month must elapse before the damage can be repaired. By to-night (17th inst.) we shall have a direct passage to the house, but the burn has to be crossed on planks, the bridge being away 'on the ocean wave.' Fully roofed tons of stones are piled up at the front and end of the house. The like was never known here nor recorded in the history of Skye."

Reports of Societies.

Cryptogamic of Scotland.—The third annual conference of this Society took place at Dunkeld last week, and though fungi were scarce, and the season rather too advanced, yet on the whole the meeting was a decided success. The proceedings may be said to have begun on Tuesday, the 16th, when some of the officials of the Society arrived at Dunkeld and had an excursion along the slopes of Birnam Hill as far as Rohallion, where, on Dr. Carrington, the well-known hepaticologist, joining them, the weather made a vigorous effort and got up a snowstorm for the benefit of the Southern visitor. The party were, however, in a mood to be content with only a limited number of "finds." The lovely scenery amongst which they strolled more than compensated for the scarcity of fungi. Had Mr. Worthington Smith been able to attend the meeting his facile pencil might have afforded the means whereby the readers of the *Gardeners' Chronicle* might have formed some idea of the country in which the Cryptogamic Society's meeting was held. For example, the place where we left the members of the Society in the midst of a snowstorm is one that cannot be easily surpassed for beauty. A picturesquely designed shooting-lodge with tower and turrets stands on a well-kept lawn on the shores of a small lakelet lying in the bosom of the hills. The lake, which is about a quarter of a mile long, is framed by a dense mass of *Rhododendrons*, which have made themselves so much at home that their seedlings can be seen springing up at the edge of the drives and walks in every direction. A small rocky and Pine-crowned island break the uniformity of the surface of the water, while fine specimens of *Abies Douglasii* and *Picea nobilis* mingle with Oaks and Birches to form a background. On one side a bold Fir-clad hill rises directly from the lake; on the other a lower and slightly more remote hill bears on its summit a ruin, which marks the site of Duncan's Castle. At the far end of the lake a tree-clothed ravine, spanned high up by a rustic bridge, leads to the brow and rocky summit of Birnam Hill. Climb to the bridge, and a great expanse of lowland scenery bursts upon the view. Around us is Birnam Wood, in front is Duncan's Castle, far in the distance we see Dunsinane Hill and Macbeth's Castle.

About sixty or seventy species of fungi were noted during the day, but none of very special interest.

On Wednesday the business of the Society properly began with an excursion in the woods to the east of Dunkeld. In addition to the President (Colonel Drummond Hay), Secretary (Dr. F. Buchanan White), and Treasurer (Rev. J. Stevenson), Sir T. Moncreiffe, Dr. Carrington (Eccles), Mr. Ogilvie (Dundee), Dr. Geikie, F.R.S. (of the Geological Survey), Mr. Sim (Banchory), and other members were present. In a wood close to Dunkeld, *Cortinarius sanguineus* was found in abundance, as also *Microspheria penicillata*, *Ucinella Wallothii*, and *U. bicornis*. At the picturesque Loch of the Lows an *al fresco* meeting of Council was held, after which an ascent of the Pine-covered rocks of Craigie Barns was made. On the way abundance of *Elaphomyces variegatus*, with its parasite, *Torrubia ophioglossoides*, was found; but the mice of Dunkeld, unlike those of Hereford, did not seem to care for Truffles. Half-way up the hill is a cave, half natural, half artificial, shaded by great trees, and with a little waterfall in it. In this cave another meeting of Council was held, to transact some business that had been forgotten. Close to the cave are some bushes of *Prunus Padus*, on which *Uredo padi* was found in abundance and fine condition. Higher up the hill abundance of snow was found, amongst which the fungi were buried. Where uncovered by the snow they were often frozen hard and brittle. At the very summit of the hill is a fine ice-smoothed and striated surface, on which rests the "Rocking Stone," a great erratic block perched upon three smaller ones. Though there is no doubt that the big stone was brought there by ice, Dr. Geikie pronounced that it had been placed by human agency upon the smaller stones, no doubt in pre-historic times. Leaving the hill, the lower grounds were searched with success, the finds including *Phelonitis strobilina*, *Polyporus intybaceus*, *Rossetia cornuta*, *Leptothyrium pictum*, *Septoria stachydis*, &c. In all, about 120 species of fungi were noted during the day.

In the evening the business meeting was held in the

City Hall, when a large audience assembled. After a number of new Fellows and Corresponding Members had been elected, the officials for 1877-78 were appointed, with Professor Balfour as President. Edinburgh was selected as the meeting-place for 1878, and September 10 and following days recommended as a suitable date. It was announced that it was intended to publish immediately, with the sanction of the Society, a set of dried specimens of Scottish fungi, especially of the new or rare species, each set to contain 100 specimens, and the price to be £1 1s. The editors of the *fasciculus* are the Rev. J. Stevenson, Glamis, and Dr. F. Buchanan White, Perth; to either of whom application should be made at once, as the number of sets will be limited. After several papers had been read a *conversazione* was held.

On Thursday morning another excursion was made. Setting out through the beautiful grounds of Dunkeld Cottage, the residence of the Duchess-Dowager of Athole, to whom the Society was much indebted for permission to go everywhere, the banks of the Tay were followed, the fine trees much distracting the attention of the members from their proper work. Many good fungi and mosses were found. Amongst the former may be mentioned *Uromyces concomitans*, B. and Br., a species first described in this journal a few years ago, and as usual mixed with *Acididium scopulariæ*, D.C. The specimens found were not growing in the circular manner described and figured in the original specimens, but had the pustules disposed in a more irregular manner. Sir T. Moncreiffe picked up a specimen of *Corticium amorphum*, growing as usual upon dead Silver Fir branches. Sir Thomas seems to have the knack of finding this species, as he has discovered it in three out of the four British (all Perthshire) localities in which it has been found. On the lawns *Geoglossum glutinosum* and *G. glabrum* abounded, and in some Spruce woods *Phelionitis strobilina*, a rare and curious fungus that grows upon the scales of Spruce cones, was not uncommon. *Agaricus sequestris*, *A. cucumis*, *Orthotrichum Lyelli*, *Tortula lævipila*, *T. papillosa*, &c., were also found. After crossing the Tay the south bank was descended, and a very fine wood of ancient Chestnuts and Oaks examined. Here *Lentinus cochleatus*, with its fragrant odour, was found not uncommonly, whilst among smaller things *Puccinia cirsii* and *Uredo padi* deserve mention. On reaching the railway tunnel at Inver search was made for the magnificent *Agaricus aureus*, which was found, but in bad condition. On the banks of the Braan, *Lycoperdon pyriforme* was seen closely covering several square yards of ground. As on the preceding day several other fungi were found, which will require further investigation.

In the evening the members of the Society and their friends dined together in the "Athole Arms" hotel. Esculent fungi were rather scarce, the more so that several specimens that had been selected for the dinner were so carefully locked away that they could not be got at in time. The following was the chief dish, and, as our gastronomic friends in Hereford may like to add the recipe to their club-book, we give it:—Take *Coprinus comatus*, *Hydnum repandum*, *Cantharellus cibarius*, and *Agaricus campestris* (adding, for the sake of flavour, if you like, *Thelephora palmeta* and *Phallus impudicus*); put them all in a dish and fill up with *Polyporus medulla-panis* of Cook(e), not of Fries; stew them together and serve hot. The *Cantharellus* is improved by being soaked all night in milk (that of *Lactarius torminosus* is not recommended).

At the dinner one member was heard gravely enquiring of a friend if he had made his will.

After dinner several toasts were drunk, including "Our friends, the Cryptogamic Botanists of England," with the hope that they would muster strong at Edinburgh next year.

On Friday the show took place in the City Hall, and, though not so large an affair as that at Perth in 1875, it was a very good show. Most of the collections were from the district, the largest being one from Moncreiffe, shown by Sir T. Moncreiffe, and including some beautiful specimens of the larger *Polypori*, as also the rare and curious *Hydaangium carneum*, hitherto only found at Glasgow.

A small table was devoted to new or very rare species, amongst which were the beautiful *Polyporus roseus* recently found at Glamis by Mr. Stevenson, who also showed *Rhizina undulata* and *Lenzites sepiaria*, the latter being more like a *Dædalea* than one of the *Agarici*. Dr. Carrington exhibited some new *Hepaticæ*, e.g., *Jungermannia nevensis*, Carr. MSS.; *Gymnomitrium crassifolium*, *Lejeunea diversifolia*, Gott.; *Riccia sorocarpa*, *R. minima*, *R. tumida*, *R. ciliata*, *R. glaucescens* (MSS.), and *R. nigrella*. Mr. Sim had a lot of rare *Sphagna*, and Mr. Sidler brought, on behalf of Professor Balfour, some *Pezize* of great interest, including *P. Adæ Sidler* (= *domicilliana*, Cooke), *P. cretea*, *P. tectoria*, and *P. cocotina*. Mr. Rogers, Manchester, showed *Chara fragifera*, recently discovered in Cornwall by Mr. Currow, a new British variety of *Mnium punctatum*, and *Bartramidula Wilsoni*.

In other parts of the show were a lot of magnificent

specimens of *Agaricus aureus*, shown by Mr. Fisher, Dunkeld Gardens; *Sprassis crispa*, of large size, from Mr. Smith, Blair Castle; *Hydnum imbricatum*, from Mr. McLennan, Ardserier, Inverness; *Fistulina hepatica*, from Iover, by Mr. C. McIntosh. Lady Kinnaird sent from Rossie Priory *Xylaria polymorpha*; and Mr. Duff, the local secretary, exhibited, in addition to a very nice collection of fungi, a curious form of *Asplenium Ruta muraria*, much approaching *A. germanicum*. We must not omit to notice that the centre of the hall was filled by a magnificent collection of living British and exotic Ferns from Dunkeld Gardens.

In addition to what we have mentioned there were many other interesting fungi.

In the afternoon the members of the Society lunched together upon *Hydnum repandum* and *Cantharellus cibarius*, a hamper of which had been sent from Glamis by Mr. Stevenson, but had arrived too late for the dinner. The poet-laureate of the Society (Mr. J. Young, C.E., of Perth) being present, delighted the company after lunch with his songs, "The Darwinian Theory" and "Menziessia cœrulea," which brought the conference to a happy termination, notwithstanding the snow and the frost. *F. Buchanan White*.

THE NEW FRENCH ROSES FOR 1877-78.—The trade in new Roses is a department in the nursery business quite by itself. It is carried on almost entirely at the great Rose establishments from which the smaller growers and the general public are supplied with these novelties as they come out year by year. Even the *dile* of English amateurs are dependent mostly upon this source for plants during the first season's issue, very few private cultivators venturing upon the expense and risk that attends speculation in such uncertainties as plants of which they know nothing except from their producers' florid descriptions. The costly nature of the importation of these novelties for propagation here may be judged when it is recollected that the usual price for each is twenty-five francs, exclusive of carriage, and that for some time, till the past two years, the number of new varieties ranged from sixty to seventy. It will be evident, therefore, that two or three hundred pounds is soon sunk, especially as from three to four plants of each variety is but a moderate allowance for propagating purposes, and that there is little prospect of recovering that outlay unless from the produce of the first season, as nine-tenths of every imported batch turn out useless here after that trial.

Notwithstanding, however, all drawbacks and discouragements, the advent of new Roses is as eagerly looked forward to by Rose culturists, professional and amateur, as the new productions in art and literature by connoisseurs. The translation, therefore, of such raiser's bits as have come to hand will be found as follows:—

BRASSAC.—H.P. Two.

Madame Theobald-Sernin.—Shrub vigorous; flowers large, full, well shaped; colour currant-red shaded carmine.

Rose à bois Jaspé.—Shrub vigorous; fine, large, green foliage; flowers large, full, globular; colour bright cherry-red, carmine (we have used this coinage as the most equivalent expression to the French term). The branches of this novel variety are ornamented with bands or stripes, yellow, red, and green, forming in their effect a remarkable marking. This peculiarity has induced us to give this Rose its name.

Hybrid Noisette.—One.

La Toulouse.—Very vigorous; flowers medium, full, well formed, flesh white, passing to clear rose. This is very free-flowering and perpetual, of the highest merit for masses.

VEUVE DUCHER.—Teas only. Three.

Mde. Maurice Kuppenheim.—Yellow salmoned, sometimes flesh-coloured, reverse of petals lightly coppered; full, fine form, very vigorous.

Louis Richard.—Coppery rose, deep red in centre; large, full, fine form, very vigorous.

Souvenir de Mlle. Marie Detry.—Light salmon-rose; large, full, fine form, very vigorous.

FONTAINE.—H.P. One.

Mde. Dortia.—Bright cherry-red, shaded purple; very large and full, opening well, growth vigorous.

Hybrid Bourbon.—One.

Angèle Fontaine.—"Carmine" red, of medium size; full, opening well; perfect form.

GUILLOT FILS.—New class of Roses; hybrids of Teas.

Mde. Alexandre Bernaix.—Deep rose, changing to striking China-rose colour, border of petals lined white; large or medium, fine shape; vigorous and superb.

Mlle. Blanche Durrschmidt.—Flesh-white, tinted salmon-rose, passing to white; medium or large, double, very vigorous; fine for bedding. Seedling from Madame Falcot. These two Roses received a silver medal this year at Lyons.

GONOD.—H.P. Two.

Mde. Jeanne Bouyer.—Fine China-rose, a new colour in this section; very large, full, well shaped; very vigorous, and a great bloomer.

Mde. Louis Donadine.—Flesh colour in the centre, lighter on the reverse side of petals. A fixed sport of Comtesse d'Oxford, the same vigour and size.

Mde. Anna de Besabrasoff.—Very bright cherry-red changing to purple; large, full, very vigorous. A seedling from Charles Lefebvre.

MDE. LÉVÊQUE ET FILS.—H.P. Four.

Edouard Dufour.—Deep crimson-red; large, full, well shaped, very vigorous. Seedling from Anna Wood. Extra variety.

Grand Duc Nicolas.—Red shaded vermilion; large, full, fine form, vigorous.

Princesse Lise Troubetzkoi.—Light rose; medium or large, well shaped and vigorous.

Princesse Charlotte de la Trémoille.—Fine satin-rose; full, globular, very free flowerer, in the way of La France.

LIADAUD.—H.P. Two.

Mde. Gabriel Luizet.—Fine satin-rose; very large, full, and vigorous.

Mde. de Laboulaye.—Light rose, deeper centre; large, full, and very vigorous.

LACHARME.—H.P. One.

Mde. François Pittet.—Beautiful white; globular, of medium size. "The finest miniature" (*sic*), "vigorous." Nothing has been forgotten in this fine plant. (M. Margottin's translation.) 1st prize at Lyons.

Tea.

Mde. Lumbard.—Fine bright red at first opening; large, full, very vigorous.

MARGOTTIN FILS.—H.P. One.

Boieldieu.—Beautiful bright cherry-red, extra large; very fine shape, very full, very floriferous, often the size of Paul Néron. Seedling from Jules Margottin. The finest Rose in cultivation of its size: grand for exhibition.

H. Bourbon.

Mde. Joubert.—Carmine-red, medium or large, late bloomer, very vigorous, good garden Rose.

Climbing Hybrid Non-Perpetual.

La Saumonnée.—Beautiful, salmon-rose, large, full, well-shaped. This variety is a seedling from a H.P., and on old plants frequently blooms again in autumn.

MOREAU-ROBERT.—H.P. Four.

Souvenir d'Adolphe Thiers.—Striking red shaded with vermilion, very large, very vigorous; seedling from Comtesse d'Oxford; first-class variety.

Mde. Roger.—Very light rose, almost white, large, full, very vigorous.

Fontenelle.—Carmine-red, very large and full, blooming in clusters, growth very vigorous.

Barthelemy Joubert.—Bright cherry-red, large, full, and very vigorous.

PERNET.—H.P. One.

Mde. Cheirot.—Salmon-rose, almost full, globular, vigorous; seedling from Victor Verdier.

Moss Non-perpetual.

Louis Gimurd.—Bright red, very large, full and vigorous.

SCHWARTZ (successor to Guillot, sen.)—H.P. Two. Alfred K. Williams.—Fine carmine-red, large, full, fine form, very vigorous.

Edouard Pynaert.—Bright currant-red, large, full, globular, vigorous, extra. Seedling from Antoine Ducher.

SOUPERT AND NOTTING.—H.P. Three.

Amœna.—Large, full, fine form, bright rose, reflexed violet; carmine-red, superb, very free flowering. Seedling from V. Verdier.

Èvêque de Luxembourg.—Very vigorous, flower large, form of *Centifolia*, deep purple-shaded violet and red-brown, centre crimson velvety, very fragrant.

Reverend Troutmann.—Large, full, well shaped; petals at the circumference bright carmine, centre very fresh rose, edged silvery, reverse of petals red lake; of great effect.

Bourbon robusta.—Very vigorous, foliage superb and grand; flower medium, well-shaped in corymbs; fiery, velvety red, changing to purple. Very effective.

VIGNERON.—H.P. Four.

Dames Patronnesses d'Orleans (what a name for it

Rose 1).—Deep crimson-red, large, full, growth vigorous.

Mde. la Marquise d'Hervey.—Velvety-red, shaded carmine, very large, full, well-formed. Growth very vigorous.

Mdlle. Anne Marie Danloux.—White, lightly tinted rosy; medium or large, full, vigorous.

Mde. Chignard.—Bright clear red, large, full, very vigorous.

These are all the raisers' lists yet come to hand. Eugène Verdier's, usually a copious issue, and Levê's, usually good, have not reached the writer. Remarks are therefore deferred to a future date.

Nothing is more tiresome than the constant iteration of the same encomiums which distinguish all new French Rose lists, at least if their producers may be believed. It must be admitted, however, that this season their flights of fancy are of more modest dimensions than usual, and that less hyperbolic phraseology sets forth their pretensions. *W. D. Prior.*

Foreign Correspondence.

MONTE VIDEO: September 2.—In your number of July 21 I read an article, by Mr. Andrew Murray, on the flow of the sap in trees, from which he appears to have satisfied himself that such flow is invariably upwards, and rejects the hitherto accepted theory that the fresh layers of wood are formed and deposited on the return of the sap downwards, after having been elaborated and assimilated by the action of the leaves. In support of his opinion he details an experiment made by him which he considers conclusive of his theory. I question whether your readers will consider the experiment of so conclusive a nature as to produce on their minds the same conviction that it has evidently produced on Mr. Murray's; and to myself, among others, there appear to be several points that require to be established before his theory can be accepted.

Even Mr. Murray will, I suppose, allow that new wood is deposited in external layers, that it is produced, as he himself says, "by the liquid parts of the sap being evaporated, the more solid part dried up, deposited, or crystallised, or what is called stored up for next year." Now what is wanting in Mr. Murray's experiments is to show the direction of depositions, whether from below or laterally. He already rejects deposition from above. To determine this important point I recommend this further experiment—namely, to tie a young branch, or, what is better, the stem of a young tree, from 1 to 1½ inch in diameter, tightly round with two or three turns of whipcord or strong durable twine, that will retain its strength during the continuance of the experiment. This should be done in early spring, before the sap begins to flow. In the course of the succeeding summer the sap will be deposited in the form of young wood—"albuminum." If it is deposited from below, the part of the stem below the ligature may be expected to be developed in greater proportion than the part above. If laterally, every part may be expected to be equally developed except that immediately embraced by the ligature. If, however, the old and formerly accepted theory should still be the true one, the deposition (or what is the same thing, the formation of new wood) would take place above the ligature, and notably so immediately above and close to it.

This experiment is constantly exhibited here by the *Dichotiscus*, an insect or caterpillar that forms a cocoon of leaf-stalks, bound together by a strong silk secreted by the insect itself. In preparation for its transformation the insect secures the upper end of the cocoon round a young branch, and so strong is the ligature by which the cocoon is attached, that on being pulled it will generally, instead of breaking, strip off both the bark and leaves from the upper part of the branch to which it has been secured.

This ligature is formed during autumn, when the circulation or movement of the sap for the season has nearly ceased, and little or no alteration in the form of the branch can be noted during the first autumn. During the following summer the change begins: an enlargement of the branch immediately above the cocoon begins to show itself, and by the end of the summer a swelling, or deposition of sap will have been formed, probably, in a fast growing tree, double the diameter of the branch immediately below the cocoon.

If during the season the ligature be not severed, the first strong wind the year following generally breaks off the branch.

A similar effect has been observed when the ligature which secured trees newly planted out to the stakes placed for their support had been left too long without being loosened.

On one occasion I planted out a *Pinus insignis*, whose trunk at 9 inches from the ground was about 2½ inches in diameter. The tree grew with amazing rapidity, and, it having been forgotten to loosen the ligature, it was found in the summer following the year in which it was planted out that, while the trunk below the ligature had only increased half an inch in diameter, the part immediately above it had acquired a diameter of 5 inches.

I am curious to know how Mr. Murray will reconcile these phenomena with his new theory of the movement of the sap.

In the same number I observe a table of the rate of growth of several descriptions of trees in a plantation or pleasure ground in North Wales, in which *Pinus insignis*, planted in 1869, had reached the height of 16 feet; certainly either the soil, or climate, or both, would appear to be unfavourable to the growth of this beautiful Conifer, as compared with our experience here. I have a group of these trees planted out when 4½ feet high, in 1868, of which the tallest is by actual measurement 50 feet high, and the average of the group is estimated at 47 feet. Many of these plants have sent out a shoot in one season over 7 feet long, and some of last year's shoots of that length were shown to a gentleman now in England—Mr. Twentyman, an enthusiastic amateur, who resides near Wolverhampton, and who, no doubt, will contradict me if I have exaggerated; Captain Fairfax, R.N., now in England, also saw the trees.

Cupressus macrocarpa, or *Lambertiana*, planted the same year, 1868, are 43 feet high, against your correspondent's 16 feet, planted in 1869; and against his *Eucalyptus*, of 15 feet in four and a half years I have 7 feet circumference of trunk at 4½ feet from the ground, and 90 feet high in fifteen years. *Thomas Tomkinson.*

- Oct. 18.—A very fine clear day. Cold. Fog and hoar-frost in morning. Lowest reading of thermometer on grass was 20°. 3.
- 19.—A fine day, but cloudy and cold. Little fog and hoar-frost in morning.
- 20.—A brilliantly fine day. Mild. Very cloudy at midnight. Lunar halo at night.
- 21.—A dull day, cloudy. Occasional slight rain in afternoon and evening.
- 22.—Fine but generally cloudy till 8 P.M., then cloudless. Occasional showers of rain.
- 23.—Overcast, dull, and wet till 4 P.M., fine and bright after. Cloudless at night.
- 24.—A very fine bright day. Cold. Rain fell between 7.30 and 9.30 P.M. Cloudless at night.

LONDON: *Barometer.*—During the week ending Saturday, October 20, in the vicinity of London the reading of the barometer at the level of the sea decreased from 29.88 inches at the beginning of the week to 29.50 inches by the early morning hours of the 15th, rapidly increased to 30.40 inches by

the evening of the 17th, and decreased to 30.13 inches by the end of the week. The mean reading for the week at sea level was 30.13 inches, being 0.01 inch above that of the preceding week, and 0.24 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 69° on the 14th to 50.3° on the 16th; the mean value for the week was 57°. The lowest temperatures of the air observed by night varied from 29° on the 18th to 53° on the 14th; the mean for the week was 38.3°. The mean daily range of temperature in the week was 18.1°, the greatest range in the day being 23.3°, both on the 18th and 19th, and the least 12.3°, on the 16th.

The mean daily temperatures of the air and the departures from their respective averages were as follows:—14th, 60°, + 9°.6; 15th, 51°, + 0°.8; 16th, 44°.5, - 5°.5; 17th, 41°.7, - 8°.1; 18th, 39°.2, - 10°.5; 19th, 43°.6, - 5°.9; 20th, 50°.5, + 1°.2. The mean temperature of the air for the week was 47°.2, being 2°.6 below the average of observations extending over a period of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 120.3° on the 14th, 112° on the 20th, and 109° on the 15th; on the 19th the highest reading was 77.3°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 20.4° on the 18th, 24.3° on the 19th, and 28° on the 17th. The mean of the seven low readings was 32.4°.

Wind.—The direction of the wind was chiefly S.S.W. and S.W., and its strength moderate, except on the 15th, when there was a very heavy gale. The weather during the week was generally dull, though fine at times. Fog prevailed on the 17th, 18th, and 19th. A lunar halo was seen on the 20th.

Rain fell on two days during the week, the amount measured was 0.07 inch.

ENGLAND: *Temperature.*—The highest temperatures of the air observed by day were 69.2° at Cambridge, 69° at Blackheath and Nottingham, and 68.3° at Liverpool; the highest temperature at Portsmouth was 61°, and at Brighton 61.3°; the mean value from all stations was 66°. The lowest temperatures of the air observed by night were 26° at Bristol, 27° at both Wolverhampton and Hull, and 29° at Blackheath, Cambridge, and Nottingham; the lowest temperature of the air at Liverpool was 38.3°, and at Portsmouth was 35°; the general mean from all stations was 31°. The range of temperature was the greatest at Bristol, 42°, and the least at Portsmouth, 26°; the mean range of temperature from all stations was 35°.

The mean of the seven high day temperatures was the highest at Truro, 58.3°, and Blackheath, Cambridge, and Plymouth, all about 57.3°, and the lowest at Bradford, 52°; the mean from all stations was 55°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 36.3°, and Bristol, 37.3°; and the highest at Portsmouth, 43.3°; the mean value from all stations was 40.3°. The mean daily range of temperature in the week was the least at Sunderland, 10.3°, and the greatest at Bristol, 19°; the mean daily range from all stations was 14.1°.

The mean temperature of the air for the week from all stations was 47°, being 6.3° lower than the value for the corresponding week in 1876. The highest was 49.3° at Truro, and 49° at both Portsmouth and Plymouth, and the lowest 43.3° at Wolverhampton, and 45.3° at both Hull and Bradford.

Rain was measured at Eccles to the amount of 1.4 inch, at Truro and Liverpool 1 inch fell, whilst at Norwich no rain fell. The average fall over the country was half an inch.

The weather during the week was generally dull, and the sky cloudy. Snow fell at Bradford on the 15th. Thunderstorms occurred at Bristol on the 15th and 16th.

Wind.—A violent gale was experienced all over the country during the night of the 14th and morning of the 15th, doing much damage, and in some cases resulting in loss of life. Lightning was seen at Liverpool on the 16th.

SCOTLAND: *Temperature.*—The highest temperatures of the air varied from 64° at Perth to 57.3° at Aberdeen; the mean value from all stations was 61.3°. The lowest temperatures of the air ranged from 28° at Dundee and Perth to 33° at Leith; the mean from all stations was 29.3°. The mean range of temperature from all stations was 32°.

The mean temperature of the air for the week from all stations was 43.3°, being 8° lower than the value for the corresponding week in 1876. The highest was 46.3°, at Leith, and the lowest 42°, at Aberdeen.

Rain.—The amounts of rain measured at the several stations during the week varied from 1.4 inch at Glasgow to four-tenths of an inch at Aberdeen; the

average fall over the country was nine-tenths of an inch.

DUBLIN.—The highest temperature of the air was 68½°, the lowest 29°, the range 39½°, the mean 49¼°, and the fall of rain 0.86 inch

JAMES GLAISHER.

Variorum.

GARDENIAS FOR CUT FLOWERS.—Gardenias are, perhaps, taken in a general way, about the worst-managed plants to be found about a gentleman's establishment, simply because they are grown in pots, either in dry hot pits or under the shade of other plants, under neither of which conditions will they thrive to any really enjoyable satisfaction.

COTTAGE NURSING.—Let me draw a little picture of the cottage where ignorance prevails. The heavy hand of sickness has been laid on the dwelling—the mother is laid low. What happens? Poor little Polly has leave to stay away from school.

between sheets of old newspaper, or botanical drying paper, laying the leaves as flat as possible, and placing above the paper a board with a heavy weight thereon.

HEATING SMALL GREENHOUSE: J. N. There is nothing so efficient and safe as a small hot-water apparatus adapted to the size of the structure, the boiler being heated by a ring of gas-burners placed in an outside "furnace," from which the gas fumes may be carried off by means of a flue pipe.

INSECTS: W. & J. B. We do not think that either of the two insects sent (both Myriapods) have had anything to do with the injury to the roots of the Larch.

PERFORATED FLOWER-POT: Crocus. The illustration given below (fig. 107) will give you an excellent idea how to plant a vase of this kind.

FIG. 108.—VASE OF SPRING FLOWERS.

sides may be planted either with Crocuses or Squills, and the top with Hyacinths, Tulips, or Narcissus.

GRAPES: W. P. D. We only know of one Black Alicante Grape, but it has many aliases. What is sometimes called the Kempsey Alicante is really the Morocco, or Black Morocco as usually so called.

NAMES OF FRUITS: F. W. P. 1, Broom Park; 2, Autumn Berganot; 3, Beurré de Capiaumont; 4, Winter Nelis.—H. A. B. 3, 9, Yorkshire Greening. Pears: 1, Catillac; 2, Glou Morceau; 3, Franc Real d'Hiver—very miserable examples.—E. H. B. 1, Hawthornden; 2, Rymer; 3, Downton Pippin; 5, King of the Pippins; 7, 8, Small's Admirable.

NAMES OF PLANTS: J. M. The Spindle-tree, Eonymus europæus.—C. E. F. Fraxinus heterophylla.—P. T. N. Silene Armeria.—C. D. Smith. We cannot determine the name of the Marrow.

RAISING CONIFERS FROM SEED: H. P. Grigor's

Arboriculture, published by Edmonston & Douglas. Seeds of various coniferous plants are sometimes sold by Mr. Stevens. Ask him to send you catalogues.

FOREIGN SUBSCRIBERS sending Post-office Orders are requested to make them payable at the post-office, King Street, Covent Garden, London, and at the same time to inform the Publisher at the office of this Journal.

Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally.

ERRATUM.—At p. 495, col. c., twelfth line from the bottom, for "regenerated" read "rejuvenated."

CATALOGUES RECEIVED.—Charles Turner (Royal Nurseries, Slough), Catalogue of Roses, Fruit Trees, Coniferae, Trees, Shrubs, Climbing Plants, &c.—T. Tucker (The Nurseries, Faringdon, Berks), Forest, Fruit, and Ornamental Trees, Shrubs, and Roses.

COMMUNICATIONS RECEIVED.—T. S. J.—J. W.—J. R. J.—W. G.—D. W. H.—J. K. D.—R. G.—B. F.—J. M.—H. P.—J. W.—J. M. C.—E. R.—W. C.—G. S.—R. D.—J. J.—E. O.—F. J. H.—W. C.—West Riding.

Markets.

COVENT GARDEN, October 25.

Our market is overdone with Apples, large quantities remaining on hand, prices for common sorts being exceptionally low. Grapes are heavy, but Pines meet with a ready sale. Kent Cobs are easily cleared at firmer rates. Business still very dull.

Table with columns for FRUIT and VEGETABLES, listing items like Apples, Grapes, Lemons, Melons, Nuts, Oranges, Artichokes, Asparagus, Beans, Beet, Brussels Sprouts, Cabbages, Carrots, Cauliflowers, Celery, Chillies, Cucumbers, Endive, Garlic, Herbs, Horse Radish, Leeks, Lettices, Mint, Mushrooms, Onions, Parsley, Peas, Radishes, Spanish, New Jersey, Salsafy, Shallots, Spinach, Tomatoes, Turnips.

Potatoes: — Essex Regents, 90s. to 110s.; Kent Regents, 100s. to 140s.; Kent Kidneys, 140s. to 160s.

Table with columns for CUT FLOWERS, listing items like Asters, Bouvardias, Calceolarias, Camellia blanda, Chrysanthemum, Cornflower, Dahlias, Eschscholtzia, Eucharis, Gardenia, Heartsease, Heliotropes, Hyacinths, Jasmine, Mignonette, Narcissus, White, Pelargoniums, Primula, Pyrethrum, Roses, Stephanotis, Stocks, Sunflower, Tropæolum, Violets.

Table with columns for PLANTS IN POTS, listing items like Begonias, Bouvardias, Chrysanth, Clematis, Coleus, Cyclamen, Cyperus, Dracæna terminalis, Eonymus, Ferns, Ficus elastica, Fuchsia, Lilium in var., Mignonette, Myrtles, Palms in variety, Pelargon, Solanum, Valotta purpur.

Enquiries.

He that questioneth much shall learn much.—E. A. O. N.

213. PURPLE IVY.—I want some plants of the purple-coloured Ivy. I have tried several nursermen without success; but am aware that one man, whose specialitè this is, can supply it. I should be much obliged if you could give me his name and address. C. H. C.

214. EARWIGS.—Can any of your correspondents favour me with their own experience of the most effectual mode of ridding a house of earwigs? In my house in Hampshire in certain summers they come into it in swarms, and no plan that we have tried has been successful in stopping their ingress. Hants.

Answers to Correspondents.

BOILERS AND HEATING: W. G. We know nothing of the boiler in question; and, as regards your heating arrangements, we would advise you to consult a properly qualified hot-water engineer.

COLOURED LEAVES.—Dry them as rapidly as possible

SEEDS.

LONDON: October 24.—No new samples of English red Clover seed yet appear; and the opinion is generally held that our home crop this year will prove exceedingly short. Nevertheless, there is scarcely any inclination to purchase foreign samples; in view of the large supplies which may presently be expected from France and America, seed merchants seem resolved to postpone operating until the consumptive period is nearer at hand. No further decline has taken place during the present week, and it may be, as many think, that the lowest point has now been reached. Mail advices just received from the Western States confirm all earlier reports as to the abundance and excellence of this year's growth; it is worth noting that whereas the price in Chicago just a twelvemonth ago was 8 dols. per bushel of 60 lb., to-day's quotation there for better seed is only 5 dols. In Trefoil there have been some more transactions at full rates. Alsike is neglected, but for white Clover rather more inquiry is felt. The moderate terms on which foreign Italian is obtainable have induced a certain amount of buying. In consequence of the recent rains winter Tares have met a revived demand. Feeding Linseed is 1s. per quarter higher. For blue Peas there is a steady sale at Monday's currencies. Bird seeds are this week without quotable variation. Moderate prices are asked for new brown Mustard seed. There is no change in the value of English Rape seed. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

At Mark Lane on Monday superior Wheats, either English or foreign, were very difficult to move, while on the sales made there was a reduction of quite 1s. per quarter. Barley was generally well held. In malt transactions were unimportant; the new produce was offered at from 69s. to 75s. per quarter. Oats were the turn dealer. Maize was in better demand, and prices advanced. Peas and beans were quiet and unaltered, while no material change took place in flour.—On Wednesday a very quiet feeling pervaded the market, business remaining particularly slow, while there was no new incident in connection with the trade upon which any important change could be established in price. Holders of the better qualities of produce, having a true knowledge of the statistical position of the trade, were not in the least anxious to realise. A large inroad will soon be made upon the heavy supplies now at hand and to come, and ultimately it is clear a scarcity will be felt of thoroughly good produce. Inferior corn may be brought occasionally on rather easier terms.—Average prices of corn for the week ending October 20:—Wheat, 52s. 9d.; Barley, 42s. 6d.; Oats, 25s. 4d. For the corresponding week last year:—Wheat, 48s. 9d.; Barley, 39s.; Oats, 24s. 8d.

CATTLE.

At Copenhagen Fields on Monday the demand for beasts was equal to the supply, and recent prices were maintained. The number of sheep was considerably larger than at last market, and there was a consequent dullness in the trade; yet choicest qualities readily made late quotations, and a fair clearance was effected. Choice calves were in demand at fully late rates. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 6d. to 6s., calves, 4s. 8d. to 6s. 2d.; sheep, 5s. 4d. to 5s. 8d., and 6s. 4d. to 7s.; pigs, 4s. to 5s.—Thursday's market was very quiet. Supplies were short, but sufficient for the demand. Five breeds, both of beasts and sheep, met a fair demand, and realised the full prices of Monday; but in other respects the tone was weak. Calves were dull, and rather less firm.

HAY.

The Whitechapel market report for Tuesday states that owing to the unsettled weather trade was very dull, and quotations were weaker. The supplies were large. Prime old clover, 100s. to 140s.; inferior, 85s. to 95s.; good new clover, 100s. to 132s.; prime meadow hay, 90s. to 110s.; inferior, 75s. to 85s.; and straw, 44s. to 55s. per load.—On Thursday a rather large supply of fodder was offered. There was a dull trade, and weather being bad, prices were again lower. (Quotations:—Prime old clover, 100s. to 138s.; inferior, 85s. to 95s.; good new, 100s. to 132s.; prime meadow hay, 90s. to 107s.; inferior, 75s. to 85s.; and straw, 44s. to 55s. per load.—Cumberland Market quotations:—Superior meadow hay, 100s. to 110s.; inferior, 80s. to 90s.; superior Clover, 128s. to 136s.; inferior, 95s. to 112s.; and straw, 54s. to 60s. per load.

POTATOS.

The Borough and Spitalfields reports state that a limited supply of Potatoes has been on sale, and the trade steady, at the subjoined currency:—Kent Regents, 140s. to 165s. per ton; Essex ditto, 120s. to 145s.; Roeks, 90s. to 105s.; kidneys, 100s. to 130s.; Victorias, 120s. to 170s.; and flukes, 160s. to 170s.—The imports into London last week comprised 46,509 bags from Hamburg, 12,154 Antwerp, 11,970 Bremen, 1388 Boulogne, 1212 Harlingen, 1142 bags 218 sacks Dunkirk, 594 bags Brussels, 148 Ghent, 510 bags 95 baskets Rotterdam, and 940 sacks and 172 tons Rouen.

COALS.

At market on Monday business was dull, through a sudden change in the weather, and the price of house coal dropped 1s. per ton. On Wednesday a further fall of 1s. had to be submitted to. Quotations:—Bower's West Hartley, 17s. 3d.; Walls End—Hetton, 21s.; Heston Lyons, 18s. 9d.; Original Hartlepool, 21s.; Tunstall, 18s. 9d.; South Kelloe, 19s. 6d.; Tees, 20s. 9d.

Important Notice to the Trade.

SEAKALE, ASPARAGUS, RHUBARB,
EXTRA STRONG ROOTS FOR FORCING.

H. THORNTON,

Having devoted great attention to the production of fine roots, and having an immense stock on hand, invites the inspection of large Buyers, or he will be happy to forward Prices for large or small quantities on application.

H. THORNTON, 12, Maxwell Road, Fulham, S.W.

COCOA-NUT FIBRE, PEAT, LOAM, SAND, all MANURES as supplied to Veitch & Sons, Carters, Wills, Bulb, Ewing, &c. Russia Mats, Raffia, and every kind of Nurserymen's and Seedmen's Sundries.
M. H. BENTOTE, 8, Castle Street, Long Acre, Covent Garden, W.C.

COCOA-NUT FIBRE REFUSE, newly made. Reduced price.—In 4 bushel bags, at 1s. 3d. (not less than 5 bags), or truck load for 20s. (truck load delivered free to rail in London). J. STEVENS AND CO., Greyhound Yard, and 134, High Street, Battersea, S.W.

PEAT.—For Sale, a quantity of Brown Fibrous and Black. For price, &c., apply to Mr. G. HILLS, Tekels Estate, Frimley, Farnborough, Hants

Fibrous Peat for Orchids, &c.

BROWN FIBROUS PEAT, best quality for Orchids, Stove Plants, &c. 66s. per truck. **BLACK FIBROUS PEAT,** for Rhododendrons, Azaleas, Heaths, American Plant Beds, 77s. per ton. Delivered on rail at Blackwater, S. E. R., or Farnborough, S. W. R., by the truck-load. Sample sack, 5s. 6d. each. Fresh SPHAGNUM, 10s. 6d. per sack. WALKER AND CO., Farnborough Station, Hants.

PEAT SOIL, PEAT SOIL.—

Brown Fibrous, good quality, for Orchids, Pot Plants, Ferns, &c., 66s. per truck. Black, good quality, for American Plants, Rhododendrons, Azaleas, Heaths, &c., 77s. per ton, or 6-ton truck for 44s. 10s. Delivered on rail at Blackwater, South-Eastern Railway, or Farnborough, South-Western Railway, by the truckload. Cash with order.

HOLDER AND SON, Crown Nurseries, Reading.

B G L OILCAKE.

ARREST YOUR PURCHASES of all other Cake until you have read the "Book of Testimonials" from users of this cake. Sent post-free by the Agent for the County, or by the Makers.
Mills, Shad Thames, London, S.E.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide, and it has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOUROUS POWDER.

Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s. 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to

AMIES' CHEMICAL MANURE CO. (LIMITED),
79, MARK LANE, LONDON, E.C.

SIMPSON'S RED SPIDER, THRIPS, &c.,

ANTIDOTE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d. Supplied to Seedsmen and Chemists. Strongly recommended in the *Gardener*, and by many first-class Gardeners.

Prepared by JOHN KILNER, Wortley, near Sheffield.

GISHURST COMPOUND.—

Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

RUSSIA MATS for Covering from Frost, from 30s. to 70s. per 100; good for packing, from 20s. GUNNY BAGS, from 3½d. each. Delivered free to any station in London.

SUTHERLAND, SON AND CO., 11, Fenchurch Buildings, Fenchurch Street, London, E.C.

RUSSIA MATS.—A large stock of Archangel and Petersburg, for Covering and Packing (price on application for Archangel)—Petersburg, 60s. to 100s. per 100, superior close-weave, 40s., 50s. and 55s. per 100; Packing Mats Mats at equally low rates, at

J. BLACKBURN AND SONS, 4 and 5, Wormwood Street, London, E.C.

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application.

Orders delivered free in London.

FISHER, CLARK AND CO., Label Works, Boston.

ESPALIER WALKS, FOR NEATLY TRAINING FRUIT TREES,

Of which figure No. 107 is a representation, and which is adapted to the Training of Apples, Pears, and other kinds of Fruit Trees, such as Raspberry, Currant, &c. The Fruit is much improved both in size and flavour by this treatment, deriving the full benefit of sun and air. As a Division for each side of a Kitchen Garden Walk, for Screening the Plots of Vegetables, especially where visitors have to pass through, their adoption is highly recommended. The Wire suitable for this purpose should be Rope or Cable Wire, on account of its neat appearance. The same being about nine inches apart, attached at each end to a strong wrought iron post, each Wire having a separate winding ratchet, can be tightened with the greatest ease when required.

No. 107.

Estimates given for the above Espalier Work on receipt of lengths required.

USEFUL AND ORNAMENTAL FOR GARDENS AND CONSERVATORIES.

IMPROVED LIGHTNING CONDUCTORS, with Fittings Complete, simple in construction and easily erected by a careful mechanic.

London Office:—No. 1, DELAHAY STREET, WESTMINSTER, S.W.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 3d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.
 "The Rylands, Alderly Edge, Manchester.—Messrs. Hill & Smith.—Sir,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted.
 —Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

JOHN BOWMAN.
 GREENHOUSES—every description, } From £10
 VINERIES—all the latest improvements, } to £100.
 GLASSHOUSES—perfect ventilation,
HORTICULTURAL BUILDER and TIMBER MERCHANT,

STEVENS' TRENTHAM GREENHOUSE BOILER,
 After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER, Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 3, 1877.
 "GENTLEMEN.—In reply to your enquiry as to our opinion of your Stevens' Trentham Boilers, we do not hesitate to pronounce them to be by far the best Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trentham Boiler, and we have now thirteen of various sizes at work. For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trentham Boilers supplied by you, and we have never felt so little anxiety in connection with our hothouses during the cold winter months as we do now.
 "We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.
 "We are, Gentlemen, yours faithfully,
 "JAMES VEITCH AND SONS."

For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER,
 HOT-WATER ENGINEERS, &c., &c.,
 Castle Hill Works, Newcastle, Staffordshire.
 Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

T. H. P. DENNIS & COMPANY.

 Specially adapted for Pumping in
 Gentlemen's Houses and Grounds.
 No Labor Required.
HAYWARD TYLER & Co.,
 84, WHITECROSS STREET, LONDON.

CRITCHLEY'S PATENT HEAT REGULATOR,
 AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.
 The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.
 The following Testimonial has been received:—
 "Berkeley Castle, April 13, 1875.
 "Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes.
 "I am, Gentlemen, yours truly,
 "R. H. CRONK,
 "Gardener to the Right Hon. Lord Fitzhardinge."
 Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

Must take charge of a Horse, and occasionally drive. Boy kept, and other assistance given. Good house and wages.—Address, with references, stating age, number of family, &c., A. E. Mr. J. Stevens, The Nurseries, Coventry.

WANTED, in Hertfordshire, a WORKING GARDENER, with WIFE to take charge of Dairy and Poultry. Good knowledge of Kitchen and Flower Garden only necessary. Must be able to take charge of Cows and Horse, and Drive Cart occasionally. To Live in Lodge or to take care of House during absence of owner. An under Gardener is kept. Apply by letter first to F. B., Jackson's Library, Albion Street, Hyde Park Square, W., stating wages and particulars of character.

WANTED, a WORKING GARDENER, who thoroughly knows his business and also something of Land and Cows. Wife capable of Managing a Dairy. No encumbrances. A Scotchman preferred. State ages and full particulars.—Apply by letter, to A. D., Messrs. Ash & Co., London Bridge, S.E.

Gardener and Wife.

WANTED, a MAN and his WIFE, without children—Man to look after small Garden, Greenhouse, Poultry, and make himself useful; Wife to assist in the House and take charge of it during absence of family. Cottage found when family at home.—Apply, by letter, stating age and wages, H. S., Messrs. Hunt & Steward, 3, Victoria Street, Westminster Abbey, S.W.

WANTED, as GARDENER and GROOM, at about 14 miles from London, a steady, married Man, without encumbrances, who thoroughly understands Gardening, can attend to a Horse, and is willing to make himself generally useful. Will have the use of two rooms over coach-house.—Apply, stating wages required, to E. K. B., Messrs. Bridger & Collins, 37, King William Street, London Bridge, London, E.C.

WANTED, an OUTDOOR WORKING NURSERY FOREMAN. Cottage provided.—W. AND J. BROWN, Nurserymen, Stamford.

WANTED, a thorough good Man as GROWER and PROPAGATOR of Market Stuff for Sale; must be a good Grower of Plants for Sale and Furnishing, also Cut Flowers all the year round; a thoroughly conscientious man, with first-class testimonials as to character and ability.—E. WHITE, The Botroemouth Nurseries, Bournemouth.

WANTED, an active, industrious MAN, who knows something of Vine and Plant Growing for Market, and is willing to make himself generally useful.—State wages and reference to W. MOLE, 50, Kennington Park Road, S.E.

WANTED, an experienced INVOICE CLERK. Salary £3 per month.—Apply, by letter, stating qualifications, addressed, B, 12, King Street, Covent Garden, W.C.

WANTED, a JUNIOR INVOICE CLERK. Salary £50 per annum.—Apply, by letter, stating experience, addressed B. S., *Gardeners' Chronicle* Office, W.C.

To the Seed Trade.

WANTED, an ASSISTANT, of good address and quick at Parcelling; also a JUNIOR CLERK, good and expert Penman.—Apply, stating references and salary required, to DICKSON and ROBINSON, Seed Merchants, Manchester.

WANTED, for a Retail Seed Business, an ASSISTANT, smart at Counter Work, and one who would make himself generally useful.—Apply, stating wages required and former experience, to FRASER and MURLEY, 90, Queen Street, Exeter.

WANTED, a SHOPMAN, accustomed to Agricultural and General Seed Trade.—Also an active MAN, accustomed to Seed Growing.—C. R. FREEMAN, Norwich.

WANTED, an UNDER SHOPMAN for one of the largest Retail Houses in the West of England.—Apply, in own handwriting, stating age, reference, and salary expected, to ROBERT T. VEITCH, 51, High Street, Exeter.

WANTED, an ASSISTANT SHOPMAN to the Seed Trade.—Apply, on Monday or Tuesday evening, to Mr. WILLIAM VATES, at "Joiland's Hotel," Falcon Street, Aldersgate, E.C.; after to G. AND W. VATES, Seed Merchants, Manchester.

Seed Trade.

WANTED, a young Man, just out of his Apprenticeship, as THIRD SHOPMAN for the Vegetable Seed Counter.—Apply, by letter, stating full particulars, salary, &c., to Mr. B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway London, N.

WANT PLACES.

E. P. DIXON can at present recommend several excellent GARDENERS, and will be pleased to answer any enquiries from Ladies and Gentlemen requiring such.—The Yorkshire Seed Establishment, Hull.

E. G. HENDERSON and SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. and Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the fitting of the situation should be left with him, so that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

GARDENER (HEAD), and GENERAL MANAGER.—JOHN TAYLOR, who has been Gardener and General Manager for the Hon. P. T. Wyndham, M.P., at Isel Hall, Cockermouth, Cumberland, for the last five years, is now open to treat for a similar situation; will be disengaged at Christmas. First-class testimonials.—Address as above.

GARDENER (HEAD).—Age 35, married, three children; a thorough man, of twenty years' hard practice in every branch.—B. D., Post-office, Chadwell Heath.

GARDENER (HEAD).—Age 28, single; well up in all branches of the profession. Good reference.—B., Post-office, Dorchester, Dorset.

GARDENER (HEAD).—Age 30; first-class Gardener and Orchard Grower. First-class references.—A. F. GORDON, E. G. Wrigley, Esq., Broad Oaks, Bury, Lancashire.

GARDENER (HEAD), where three or more are kept.—Age 26, married, no family. For full particulars apply to J. W., The Gardens, Colley Manor, Reigate, Surrey.

GARDENER (HEAD), to any Gentleman requiring the services of a practical, energetic and trustworthy Man.—Age 38, married. First-class references from present and former situation.—W. L., Barrow Hills, Long Cross, Chertsey.

GARDENER (HEAD).—Age 41, married, no family; well experienced in all branches of the profession. Four years' good character. Wife a good Dairy-woman. No Single-handed place accepted.—W. P., Room's Cottages, Garlands Road, Redhill.

GARDENER (HEAD), age 32.—D. KNIGHT, for the last six years Gardener to Captain Dixon, Astle Park, Chelford, Crewe, is at liberty to engage with any Lady or Gentleman requiring the services of a man thoroughly practical in all branches of Gardening; competent to undertake any Improvement connected with a Gentleman's Establishment where energy and intelligence are required. First-class references.—Address as above.

GARDENER (HEAD, WORKING).—Please state wages and particulars to C. T., 2, Dunger Place, Colney Hatch, Middlesex, N.

GARDENER (HEAD, WORKING).—Age 36, married, no family; thorough practical knowledge of the profession in all its branches. Good character from last and previous situations.—H. L., 5, Lower Orchard Street, Lyham Road, Brixton, S.W.

GARDENER (HEAD, WORKING), where two or three are kept, or FOREMAN in a first-rate Establishment.—Age 25, single. Can produce first-class testimonials.—State wages and particulars to THOMAS BENNETT, Bishopston, Stratford-on-Avon.

GARDENER (HEAD, WORKING).—Age 30, married; thoroughly understands Forcing of all kinds of Fruit, Flowers, and Vegetables, Stove and Greenhouse Plants, Flower and Kitchen Gardening. Can be highly recommended. Please state wages, &c.—W. DANIELS, Southend, Catford Bridge, Kent, S.E.

GARDENER.—JOHN COWAN, The Vineyard, Garston, near Liverpool, would be glad to recommend to any Nobleman or Gentleman requiring a first-class Gardener a Man in the prime of life, who thoroughly understands the profession in all its branches, having had many years' experience in some of the best places in England and Scotland.

GARDENER (SECOND, or SINGLE-HANDED).—Age 20; five years' experience. Good character.—C. E., Grove Cottage, Northiam, Sussex.

GARDENER (SECOND), in a Nobleman's or Gentleman's Establishment.—Age 23, single; well up in Forcing Fruits, Flowers, and Vegetables. Two years in last place as Second. First-class character.—B. D., Sutton Park, Guildford, Surrey.

GARDENER (UNDER), in a good Establishment.—Age 23; six years' experience in all branches. Good testimonials.—Particulars to GEORGE BLACKMOOR, 6, Orchard Street, Kensington, London, W.

GARDENER (UNDER), in the Houses preferred; age 21.—J. STAVINSON, Gardener, Clifton House, Rotherham, Yorkshire, will be glad to recommend a young Man as above.

GARDENER (UNDER), in a good Establishment.—Age 22; eight years' experience in all branches of the profession. Good references.—Address, stating wages, &c., to A. B. C., 1, Holly Cottages, Little Hill, Middlesex.

JOURNEYMAN, in a Gentleman's Garden.—Young; six years' good experience, and two years and eight months excellent character from last place.—J. BUTLER, 71, Warden Road, Kentish Town, London, N.W.

FOREMAN, in a Nobleman's or Gentleman's Garden.—Age 25; has a thorough knowledge of Fruit Forcing, Plant Growing, &c. Good reference.—E. R., The Gardens, Cole Orton Hall, Ashby-de-la-Zouch.

To Nurserymen.

FOREMAN (WORKING).—The Advertiser, who has had eighteen years' experience in several well-known London Nurseries, is desirous of a re-engagement where Plants are grown largely; thoroughly understands the Cultivation and Forcing of Stove, Soft-wooded, and Bulbous Plants. Is well up in the Market and Furnishing Trades. Would undertake the Management of a Branch Nursery. For a place of trust a guarantee of £250 can be given if required. Will be disengaged November 7. Undeniable references from previous employers.—A. W., 16, Milton Road, South Hornsey, N.

PROPAGATOR and GROWER of Soft-wooded and Other Plants, Stove Plants, Bouvardias, Cytisus, &c.—Has had great experience for the past thirteen years in the Public Parks of London, and also in the Trade. Good character from last and previous employers.—P. C., 7, Canterbury Grove, Lamsdown Road, Lower Norwood, S.E.

IMPROVER, in a good Establishment.—Age 20; good reference.—A. A. H., The Gardens, Elsham House, Grantham.

IMPROVER.—A Youth, son of a Nurseryman, seeks employment in a Leading Nursery, or where Fruit is grown extensively; would devote his time and energy to the interests of his employer, and would be willing to make himself useful in any capacity.—B. M., Messrs. Flanagan & Son, 98, Chéapside, London, E.C.

To the Nursery and Seed Trade.

CORRESPONDING CLERK, or BOOK-KEEPER.—Age 27; considerable experience in first-class Houses. Good references.—A. K., 118, Kensington Park Road, London, W.

JAMES EPPS & CO.,
HOMŒOPATHIC CHEMISTS.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, COLIC, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.

DINNEFORD AND CO.,
172, New Bond Street, London, and all Chemists.

Another Cure of Bad Throat, Cough, &c. (this week) by DR. LOCOCK'S PULMONIC WAFERS.—From Mr. HERON, 10, Arthur Street, Belfast, October 11, 1877.—"I am subject to inflammation of the throat, and suffer greatly in cold weather from a cough. Dr. Locock's Wafers relieved the cough, allayed the inflammation, and gave me ease at once." Asthma, Consumption, Bronchitis, Coughs, and Colds, are instantly relieved and rapidly cured by the Wafers, which taste pleasantly. Sold at 1s. 1/6d. and 2s. 9d.

HOLLOWAY'S PILLS.—The extraordinary range of temperature prevailing in our climate is extremely trying to the delicate-constituted, the weak and nervous. All troubled by these affections should resolve to resort to this strengthening and regulating Medicine immediately they perceive in themselves discomfort or that feeling of restlessness which betokens disordered digestion and defective secretion of bile. One of Holloway's Pills taken about noon, and followed at bedtime by a dose sufficiently large to act aperiently, will speedily recruit the faulty functions, and restore order throughout the whole system. A treatment so safe in operation and so successful in result should be known and practised when, from cold and sundry other causes, disease is attempting to gain a vexatious footing.

Send for a PRICE LIST of

BLAKE'S SELF-ACTING HYDRAULIC RAMS,

For Raising Water for the Supply of
Villages, Irrigation, Railway Stations, Manstons,
Fountains, Farms.

No Cost for Motive Power, which is obtained from the
Stream of Water passing through the Rams.

NO OILING OR PACKING REQUIRED.

Made in sizes to raise from 300 to 100,000 Gallons per day.

WILL FORCE TO A HEIGHT OF 1,500 FEET.

This advertisement will
appear again in three weeks.

This Ram will raise a part of the same water that works it, or will raise pure water from a well whilst it is worked by a stream of impure water.

TESTIMONIALS.

From the Right Hon. T. SOTHERN ESTCOURT, *Estcourt Park, Gloucestershire, September 6, 1875.*

"You will be glad to hear, as I am to tell you, that your Self-acting Hydraulic Ram has worked exceedingly well and continuously since it was erected, more than twelve months ago. It is, in fact, perfectly successful."

(The delivery pipe in the above case is 4200 feet long, with 100 feet rise.)

From Captain TOWNSHEND, *Winclem, February 10, 1877.*

"In answer to your inquiry, I am glad to say the Hydraulic Ram you sent me in November, 1875, is working exceedingly well, and gives no trouble. It will work when quite immersed, as it has been several times during the floods this winter, forcing up water through a delivery pipe 900 yards long at the rate of 80,000 gallons per day, although you only promised 50,000."

From JOHN BARNES, Esq., *Contractor, Chaburn and Helli-feld Railway, Contractor's Office, March, 1877.*

"Dear Sir,—I have the pleasure to inform you that the three Hydraulic Rams you erected for me on this contract about two years ago, have continued to work very satisfactorily, without requiring any repairing. With a fall of 5 feet sufficient water has been raised daily by each Ram to supply two of my locomotive engines: they have fully answered my expectations and all that has been said of them."

Deanwater, Wilmslow, November 20, 1873.

"Dear Sir,—In answer to your inquiries respecting the Hydraulic Ram you supplied me with six months ago, I beg to state that I am more than satisfied with it, as it is in perfect order, sending up to the top of the house about 2000 gallons of water in the twenty-four hours, whereas you only contracted to deliver in that time 500 gallons. I have, therefore, every reason to be well pleased with your work, and more especially as I had a Ram supplied me by another maker which could not send up a single gallon of water to the height required, and a second maker informed me that no Ram with a fall of 3 feet could send up water to the distance required, namely, 120 feet. But yours is an accomplished fact, and does its work most effectually.—I am, yours truly, L. HAMMER."

From Mr. THOMAS MASON, *Alkinoates Hall, Colne, September 30, 1871.*

"Sir,—Your self-acting Hydraulic Ram gives me entire satisfaction; it has been at work about fifteen months, and has only been seen once during the last six months; it is forcing about 1400 gallons per day of twenty-four hours to a height of 194 feet."

From JOHN PENNINGTON, Esq., *Emmott Hall, near Colne, December 21, 1868.*

"Sir,—The Self-acting Hydraulic Ram you supplied me with nine months ago continues in excellent condition. It receives water from a spring through a 2-inch pipe, of which it forces 3500 gallons per day of twenty-four hours to a height of 90 feet, exceeding all you promised, and far surpassing the water-wheel and force pumps which it has displaced. Its cost is small, it occupies but little space (2 square feet), and in mechanical detail is simplicity itself. I have much pleasure in recommending it as a cheap and efficient method of raising water."

JOHN BLAKE,
ENGINEER, ACCRINGTON.

IMPORTANT AUCTION SALE.

Established and Imported Orchids.

MR. J. C. STEVENS will **SELL** by **AUCTION**, at his Great Rooms, 38, King Street, Covent Garden, W.C., on **TUESDAY, November 13**, at half-past 12 o'clock precisely, 30 Plants of **PHALÆNOPSIS SCHILLERIANA** and **AMABILIS**; several small collections of Established **ORCHIDS**, comprising many choice sorts; several importations, including *Cattleya Aclandiae*, *Galeandra Devoniensis*, *Cattleya maxima*; a small collection of **STOVE and GREENHOUSE PLANTS**, 20 small Plants of **BAKERIA ELEGANS**, 1000 the Bulbs of **LILIUM AURATUM**, just arrived from Japan.

On view morning of Sale, and Catalogues had.

Beverley.

An Important Property, well known as the Norwood Nurseries, situate on the south side of Norwood, in the occupation of Mr. W. E. Dixon, the owner.

N. EASTON and SON are instructed by the Proprietor, who is leaving Beverley, to **SELL** by **AUCTION**, at the "Holderness Hotel," Beverley, on **THURSDAY, November 8**, at 3 o'clock P.M., and subject to conditions which may be inspected prior to the Sale, the valuable **FREehold PROPERTY** known as the Norwood Nurseries, situate on the south side of Norwood, Beverley, in the immediate vicinity of the centre of the town, and consisting of a commodious Family Residence, containing spacious Drawing and Dining Rooms (the latter 24 feet by 16 feet), Library, two Kitchens, six Bed and two Dressing Rooms, two Attics, w.c., and the usual Domestic Offices; the extensive range of modern Buildings, consisting of a Sale Shop, Warehouses, Offices, Stables, Coach House, Harness and Van Shed, &c.; a noble Conservatory, of recent erection, and fitted on the most approved principles, size, 50 feet by 40 feet; thirteen Greenhouses, about 1750 feet in length, containing about 12,500 superficial feet of Glass, the whole heated by about 3000 feet of 4-in. piping; four Potting Sheds, and the extensive and well laid out Nursery Grounds, the area of the whole being about 7260 square yards, with a frontage to Norwood of 87 feet or thereabouts.

The situation of the property is a most central one for the extensive business now being carried on, and the present Sale offers a most favourable opportunity for purchase to any person wishing to embark in the Nursery and Seed Business. The property is also well worthy the attention of Speculators and Others, as a large portion of the land might be utilised for Building Purposes. Early Possession can be given.

N.B.—This Sale does not include the Nursery Stock.

For plans and further particulars application may be made to the Auctioneers, Bowllay Lane, Hull; to Mr. W. E. DIXON, on the Premises; or to **SHEPHERD, CRUST, TODD, and MILLS**, Solicitors, Beverley.

Unreserved Sale of a Large Consignment of Choice selected **HYACINTHS** for Pots or Glasses, **TULIPS, CROCUS, POLYANTHUS, LILIES, GLADIOLI, SNOWDROPS**, and other **BULBS**, from Holland.

MESRS. PROTHEROE and MORRIS will **SELL** the above by **AUCTION**, at the Mart, Tokenhouse Yard, near the Bank of England, London, E.C., on **MONDAY NEXT**, at half-past 12 o'clock.

Catalogues may be had of the Auctioneers, 98, Gracechurch Street, London, and Leytonstone, Essex.

Highgate, N.

CLEARANCE SALE of a fine assortment of **EVERGREEN CONIFERÆ** and **DECIDUOUS SHRUBS**, comprising several fine specimens and a quantity of Border **SHRUBS** and other useful stock; a fine assortment of **AMERICAN PLANTS, STANDARD ORNAMENTAL TREES**, selected **FRUIT TREES**, fine Standard and Dwarf **ROSES**.

MESRS. PROTHEROE and MORRIS are instructed by Mr. Eagles, who is retiring from business, to **SELL** the above by **AUCTION**, without reserve, on the Premises, the Nursery, Southwood Lane, Highgate, close to Highgate Station, on **FRIDAY, November 9**, at 11 o'clock precisely.

May now be viewed, and Catalogues had of the Auctioneers.

Woking.

CLEARANCE SALE of **NURSERY STOCK**, by order of the Executors of the late Mr. William Collyer.

MESRS. PROTHEROE and MORRIS are instructed to **SELL** by **AUCTION**, on the Premises, the Horsell Birch Nursery, Horsell, about 1 mile from the Woking Station, Surrey, on **TUESDAY, November 13**, and two following days, at 11 for 12 o'clock precisely each day, a large quantity of well-grown **NURSERY STOCK**, comprising 40,000 Green Hollies, including many fine specimens; 18,000 English Yews, 18 inches to 5 feet, 1000 variegated; 5500 Portugal Laurels, 2 to 5 feet; 10,000 Common Laurel; 1000 Aucubas, Laurustinus, and numerous other Shrubs; 1500 Standard Roses; 100,000 Fruit Stocks, 800 Daphne indica, 1000 Horse Chestnuts and large quantities of other useful stock in capital condition for removal.

N.B. This Sale is specially attractive to Contractors, Builders, the Trade, and to others engaged in making extensive plantations.

The Stock may be viewed any day prior to the Sale. Catalogues may be had on the Premises, of Mr. KNOWLES, and of the Auctioneers and Estate Agents, 38, Gracechurch Street, E.C.

Edgware, N.W.

IMPORTANT CLEARANCE SALE of **VALUABLE NURSERY STOCK**.

MESRS. PROTHEROE and MORRIS will **SELL** by **AUCTION**, on the Premises, the Whitchurch Rectory, Edgware, on **FRIDAY, November 16**, at 12 for 1 o'clock precisely, a portion of the valuable and remarkably well-grown **NURSERY STOCK**, comprising a great variety of handsome **Lawn Trees**, a splendid assortment of other Coniferæ and Evergreen shrubs, which have all been recently transplanted, together with a fine collection of Orchids, and a number of Camellias and other Greenhouse Plants.

May be viewed the day prior to the Sale. Catalogues may be had of the Auctioneers, 98, Gracechurch Street, E.C., and Leytonstone, E.

Thames Ditton, Surrey.

CLEARANCE SALE of a large quantity of very useful and well-rooted **NURSERY STOCK**. By order of the Executors of the late Mr. J. Lewis.

MESRS. PROTHEROE and MORRIS will **SELL** by **AUCTION**, on the Premises, the Ember Nurseries, Thames Ditton, on **TUESDAY, Nov. 10**, and following days, at 11 for 12 o'clock precisely each day, the whole of the valuable **NURSERY STOCK**, consisting of a large and varied assortment of choice Evergreen and Coniferæ shrubs, ranging all sizes, and adapted for immediate effect. Also 8000 Common Laurels, 2 to 7 feet; 1500 Cupressus Lawsoniana, 2 to 10 feet; 500 Thujaopsis borealis, 2000 Thuja Lobbi, 2 to 10 feet; 1000 Gold and Silver variegated Hollies, 1 to 3 feet; 1000 Standard Ornamental Trees, and a great variety of Fruit Trees.

May be viewed prior to the Sale. Catalogues may be had of the Auctioneers, 98, Gracechurch Street, E.C., and Leytonstone, E.

N.B. The LEASE of the **NURSERY**, which comprises Dwelling-house, Seed-shop, 9 Acres of productive Land, several modern Glass Erections, containing about 11,500 feet of glass, together with the Indoor Stock, Seeds, Shop Fixtures, &c., are to be **SOLD BY PRIVATE TREATY** on easy terms.—Apply to the Auctioneers for further particulars and price.

The Potteries, Ilkeston.

To **NOBLEMEN, GENTLEMEN, NURSERYMEN, FLORISTS, and OTHERS.**

MR. WRIGHT LISSETT begs to announce that he is honoured with instructions from Richard Evans, Esq., to **SELL** by **AUCTION**, at his Gardens, the Potteries, Ilkeston, on **MONDAY, November 5**, at 11 o'clock precisely, the whole of his very choice collection of **CAMELLIAS, STOVE and GREENHOUSE PLANTS, and FERNS**; also all the **HOUSES, GREENHOUSES, and a splendid CONSERVATORY**, with the Heating Apparatus and Fittings belonging to each; likewise sixty-four **GREENHOUSE LIGHTS**, 7 feet 6 inches by 4 feet, quite new, suitable for Garden Frames; quantity of **FLUE COVERS** 18 by 9 inches, ditto, 18 by 12 inches; patent Garden **ROLLER**, by Tindale; large Iron **TANK**, and various other items.

The Camellias, for which Mr. Evans has long been noted, are in robust health, and well set with Blossom, and altogether a very fine collection, as well as the largest in the district for many miles round. The conservatory is nearly new, of artistic beauty, and in good condition, built from a design by Mr. Foster. One of the Vineries is equal to new.

Catalogues will be ready seven days prior to the Sale, and may be had at the place of Sale, and of the Auctioneer at his offices, Town Hall, Ilkeston, and Maypole Yard, Nottingham, on Saturdays.

Farfield House, Armley, Leeds.

MESRS. HEPPER and SONS beg to give notice that they are instructed by Mrs. Wood to **SELL** by **AUCTION**, on **TUESDAY, November 6**, commencing at 11 o'clock, the well-known Collection of **STOVE and GREENHOUSE PLANTS**, embracing very choice specimens of the following kinds, viz. — In **AZALEAS**—Chelsoni, Rubens, Duchesse Adelaide de Nassau, Duc de Nassau, Apollonia, William Bull, Stella, Perfection, Mrs. Fry, Souvenir de Prince Albert, &c. In **CAMELLIAS**—Henri Favre, Marchioness of Exeter, Mathotiana, &c. In **PALMS**—Dæmonorops fissus, Areca aurea, Areca lutescens, Areca Verschaffeltii, Euterpe edulis, Cocos Weddelliana, Lantana borbonica, &c. In **FERNS**—Selaginella denticulata, robusta and Willdenowii, gymogramma, Platycerium alcincore, Adiantum formosum, farleyense, cuneatum, &c.

Also a great variety of **Ericas, Dracænas, Yuccas, Spiræa japonica, Clerodendrons, Crotons, Orchids, Poinsettia pulcherrima, Stephanotis floribunda, Anthurium Scherzerianum, Gloxinias, Dipladenias, Pimeleas, Euphorbias, &c.**

Plants from this collection have been frequently exhibited at Leeds, York, and elsewhere, and the owner has been awarded numerous leading prizes.

Catalogues are now ready, and will be forwarded to applicants.

The plants can be seen by holders of Catalogues only on application to the Gardener, **ROBERT SLEIGHTHOLME**, on Monday, November 5, between the hours of 10 and 4 o'clock.

To Gentlemen Engaged in Planting.

Magnificent Specimen **EVERGREENS**, comprising Wellingtonias, Cupressus Lawsoniana, Thujaopsis boreale, Golden Yews, Cedrus Deodora, &c., from 6 to 12 feet high, all grown singly, and will lift with large balls of earth; also **ROSES, RHODODENDRONS, THUJAS**, and other choice Trees and Shrubs.

MESRS. OLIVER, NEWBOLD, and OLIVER have received instructions from Mr. E. Cooling to **SELL** by **AUCTION**, as above, at the Mile Ash Nursery, Derby, on **TUESDAY and WEDNESDAY, November 13 and 14**, at 11 o'clock.

Catalogues may be had at the Offices of the Auctioneers, Warwick; or from Mr. E. COOLING, 18, Irongate, Derby.

Swiss Nursery, Loughborough Road, Brixton, S.W.

(Close to the Loughborough Junction Station.)

MR. W. ABRAHAM is instructed to **SELL** by **AUCTION**, on the Premises, as above, on **SATURDAY, November 17**, at 1 o'clock precisely, a choice and varied assortment of **NURSERY STOCK**, including some fine *Cryptomeria elegans*, Junipers, Yew, Pampas Grass, Cupressus, Gold and Silver Holly, Standard and Dwarf Roses, Coniferæ and Evergreens in pots, large Myrtles, Palms, Agave, Oleander, trained, pyramidal and bush Fruit Trees, and many others.

Catalogues one week before the Sale, on the Premises; or of the Auctioneer, Goldworth Nursery, Woking, Surrey.

To Florists.

A SMALL BUSINESS REQUIRED, the neighbourhood of London preferred; or a **SMALL HOUSE**, with **GROUNDS** suitable for the purpose.

A. B., 8, Beaufort Buildings, Strand, W.C.

To Florists, Seedsmen, &c.

FOR SALE, by Private Treaty, the **BUSINESS** of a Nurseryman, Seedsmen, and Florist, carried on by William Rushforth (formerly by Mr. Kearsley) for many years at Leeds, together with the **STOCKS** at the Nursery at Woodhouse Hill and Shadwell. WARE has pleasure in announcing that the above new CATALOGUE is now ready; it includes Winter-Flowering Carnations and Pinks, Fancy, Self and Show Pinks, Daisies, Pansies, Pæonies, Phloxes, Violas, Violets, &c. Free on application. Hale Farm Nurseries, Tottenham, London.

MYROBALAN, or CHERRY PLUM, is the best stuff for Mending Old Fences or Making New Ones. It grows vigorously in the poorest soils, even where Whitethorn will hardly exist, and bears clipping like Whitethorn. Its stiff hard branches, and dangerous spines or thorns, effectually prevent cattle or evil-disposed persons from getting through Fences made of it. Plant from four to six in a yard. Sizes and prices on application to E. WING AND COMPANY, The Royal Norfolk Nurseries, Eaton, near Norwich.

PETER DE COCK AND COLUMBIEN, The White Flower Nursery, Meirelleke, Ghent, Belgium, offer to the Trade: SPIRÆA JAPONICA, forcing clumps, 14s. per 100, £6 per 1000. DEUTZIA GRACILIS, for forcing, 18s. per 100, £8 per 1000. HELLEBORUS NIGER (Christmas Rose), for bloom, 14s. per 100, £6 per 1000. CAMELIAS, AZALEAS, PALMS, FERNS, &c.

Kent—The Garden of England. THOS. BUNYARD AND SONS offer the fine Stock in the Trade of 10,000 Standard CHERRIES, 15,000 Standard PEARS, 1,000 Standard MULBERRIES, KENT COB NUTS, and other FRUIT TREES. Prices of which may be found in their Trade LIST, just published. Also cheap and fine AUCUBAS, 2 to 6 feet; trained PLUMS and PEARS; RHODODENDRON PONTICUM, SPRUCE, BIRCH; YUCCAS, ELMS, LIMES, and other FOREST TREES, CLIMBERS, &c. THOS. BUNYARD AND SONS, The Old Nurseries, Maidstone, Kent.

HOTEIA (SPIRÆA) JAPONICA.—100,000, in very strong and sound condition. SPIRÆA JAPONICA, 16s. to 20s. per 100; have been awarded several First Prizes, and always considered best shown. DIELYTRA SPECTABILIS, very strong, 20s. to 26s. per 100. LILIUM LANCI-FOLIUM ALBUM MONSTROSUM, 30s. to 40s. per 100; very free flowering. " ROSUM, strong, 20s. to 26s. per 100. " RUBRUM, strong, 20s. to 26s. per 100. " CHINENSIS TIGRINUM, 5s. to 7s. per 100. Trade Catalogues on application. Post-office Order or good reference from unknown correspondents. BUDDENBORG BROS., Nurserymen, Hillegom, near Haarlem, Holland.

Vines—Vines—Vines. B. S. WILLIAMS begs to announce that his VINES this year are in unusually fine condition, and are now ready for distribution. NEW LATE-KEEPING BLACK GRAPE, "ALNWICK SEEDLING."—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well till February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-class Certificate. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 21s. and 42s. each. For Detailed List see BULB CATALOGUE. NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 21s. each. B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

To the Trade. JOHN PERKINS AND SON beg to offer the following, the whole of which have been recently removed, and are fine healthy plants:— ABIES DOUGLASSII, 4 to 5 feet, 6s. per dozen. ACER NEGUNDO var., Pyramids, 40s. per 100. ABIES MENZIESII, 4 to 5 feet, 18s. per dozen. CEDRUS DEODARA, 2½ to 3 feet, 21s. per dozen. HOLLY, Gold Queen, 1½ to 2 feet, 18s. per dozen. LIMES, fine Standards, 10 to 12 feet, 12s. per dozen. LAURELS, Common, 2 to 2½ feet, 12s. per 100; 100s. per 1000. LAURUSTINUS, 1½ to 2 feet, 40s. per 100. PICEA NOBILIS, 2 to 2½ feet, 30s. per dozen. " PINSAPO, 2 to 5 feet, 24s. per dozen. " NORDMANNIANA, 3 to 5 feet, 30s. per dozen. PINUS EXCELSA, 4 to 5 feet, 18s. per dozen. CEMBRA, 4 to 5 feet, 60s. per 100. LAURELS, Portugal, 3½ to 4 feet, 70s. per 100. THUJA AUREA, 1 foot, 50s. per 100. Wholesale and Retail CATALOGUES on application. 52, Market Square, Northampton.

To Exhibitors and Others. STOVE PLANTS.—Large specimens to be disposed of, on account of not having sufficient room to house them:— PANDANUS VEITCHII, 4 feet high and 6 feet through, and 5 feet high and 6 feet through. CROTON INTERRUPTUM, fine specimen, well coloured, 6 feet by 6 feet. UNDLATUM, 5 feet by 5 feet. ALOCASIA METALICA, 2 feet by 4 feet. MARANTA ZEBRINA, 3 feet by 6 feet. " VEITCHII, good half-specimen. " ROSEA PICTA. Also the following healthy and useful WINTER FLOWER-ING PLANTS:—Solunums, Bouvardias, Libonias, Eranthemums, Limnons, Gardenias, Erica hymenialis, gracilis, Caffra, and other varieties: Camellias, Azaleas, Cyclamens, Poinsettias. Now being the time to obtain stock of the following Carpet Bedding Plants, W. MILES can supply Alternanthera, Antennaria, Arenaria, Achillea, Cerastium, Leucophytum, Mentha, Mesembryanthemum, Nertera, Sagina, Santolina, Tecoma, Echeverias, Sempervivum, &c. All particulars and prices on application to W. MILES, West Drighton Nursery, Cliftonville, Sussex.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOROUS POWDER.
 Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.
 Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to AMIES' CHEMICAL MANURE CO. (LIMITED), 79, MARK LANE, LONDON, E.C.

Decorticated Cotton Cake of the Best Quality (PRIME BRIGHT CAKES), can be obtained from the AGRICULTURAL and HORTICULTURAL ASSOCIATION (LIMITED), 47, Millbank Street, Westminster, London, S.W. Delivered from their several depots, as follows, viz.:— LONDON, SOUTHAMPTON, LIVERPOOL, TOTNES, BRISTOL. Prices and samples sent on application.

GISHURST COMPOUND.—
 Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application.

Under the Patronage of the Queen.
J. SMITH'S IMPERISHABLE STRATFORD LABELS.

The above Labels are made of a White Metal, with RAISED BLACK-FACED LETTERS. The *Gardeners' Magazine* says:—"We must give these the palm before all other plant labels, as the very first in merit."
 Samples and Price Lists free.
 J. SMITH, The Royal Label Factory, Stratford-on-Avon.

B. WHITHAM, The Nurseries, Reddish, near Stockport, has for Sale—
50,000 ENGLISH YEWs, extra fine, many times transplanted, 1 to 2 feet, 20s. per 100; 2 to 3 feet, 40s. per 100; 3 to 4 feet, 60s. per 100. Great reduction to purchasers of 1000 and upwards.
Also to be sold cheap many Thousands of HORSE CHEST-NUTS and LIMES, 8 to 10 feet, fine for avenues.

For the best List of Choice Hyacinths, Tulips, Crocuses, Narcissus, &c., see our Beautifully Illustrated

CATALOGUE
OF
DUTCH FLOWER ROOTS

FOR
Autumn, 1877,

Containing numerous fine Engravings and much Valuable and Original Information on the successful Culture of Bulbous-rooted Plants. Should be read by all intending purchasers before ordering. Post-free on application.

Our
21s. Collection
(No. 7).

For outdoor or open border decoration, contains the following liberal assortment:—

- 25 Hyacinths, choice mixed
- 18 Polyanthus Narcissus, mixed
- 12 Narcissus Poeticus
- 12 " double white
- 6 Campernelle Jonquils
- 25 Anemones, fine double
- 50 " fine single
- 50 Persian Ranunculi, mixed
- 50 Turban Ranunculi, in 4 varieties
- 150 Crocus, in 6 vars.
- 100 Snowdrops
- 12 Tulips, scarlet Van Thol
- 12 " Cottage Maid
- 25 " Yellow Prince
- 25 " double, mixed
- 12 " Rex Rubrum
- 12 " late, mixed
- 12 Scilla amœna
- 2 Lilium candidum
- 12 Spanish Iris
- 9 Herbaceous and Alpine Plants,

WITH FULL CULTURAL DIRECTIONS.

Case, Packing, and Carriage Free to any Railway Station in England and Wales.

Other Collections, for Greenhouse or Conservatory, &c., 12s. 6d., 21s., 42s., 63s., and 84s. each.

From Mr. H. BENNETT, Belle Vue Crescent, Clifton, Bristol. March 10, 1877.

"I am glad to tell you that the Hyacinths, Tulips, and Crocus I had in the Autumn have given entire satisfaction; the flowers are splendid."

From R. PRYNOCE, Esq., Bathgate, N.B. February 7, 1877.

"The Bulbs received from you in the Autumn have been particularly fine; some of the Hyacinths and Tulips now in bloom are large and beautiful, and have far exceeded any that I have had before."

DANIELS BROS.,
THE QUEEN'S SEEDSMEN, NORWICH.

WM. PAUL & SON,
(Successors to the late A. Paul & Son, Established 1806.)

ROSE GROWERS,
TREE, PLANT, BULB, AND SEED MERCHANTS,
WALTHAM CROSS,
HERTS,

Adjoining the "Waltham" Station, Great Eastern Railway.

Inspection of Stock invited.

Cabbage Plants, Cabbage Plants.
W. VIRGO AND SON can now supply in any quantity good strong, healthy plants, viz., Early Battersea, Early Enfield Market, Early Nonpariel, and Sugar-loaf Cabbages, all at 3s. per 1000; Robinson's Drumhead, 3s. per 1000; Red Drumhead, 5s. per 1000; delivered free on rail. Post-office Orders must accompany all orders from unknown correspondents.
W. VIRGO AND SON, Womersley Nursery, near Guildford.

STONE'S APPLE.—As Certified by the Royal Horticultural Society, and shown at the Crystal Palace. A very handsome Kitchen Apple, of large size and a great bearer. True to name. Fine 2-yr. trees, 42s. per dozen. Trade price on application.
THOS. BUNYARD AND SONS, The Old Nurseries, Maidstone, Kent.

SEEDLING PLANTS.—**HOLLYHOCKS**, fine strong seedlings, 2s. 6d. per dozen; **PANSIES**, 1d. each from 1 to 10,000; **CARNATIONS**, 1d. each from 1 to 10,000. Bulb CATALOGUE on application.
BIDDLES AND CO., Loughborough.

Cytisus, Cytisus, Cytisus.
FOR SALE, good stuff, in thumb-pots, 20s. per 100, or 2s. per 1000; special prices for larger quantities. Also **LYCOPodium DENTICULATUM**, good, in 48s, 25s., and large 60s, 20s. per 100. For Cash only.
F. C. BÖFF, 17, Magdala Road, Upper Holloway, N.

NEW HARDY RHODODENDRONS.—**MRS. MENDEL SIGISMUND RUCKER MARCHIONESS OF LANSDOWNE**
The above beautiful and distinct hardy Rhododendrons will be supplied for Three Guineas.
ANTHONY WATERER, Knap Hill, Woking, Surrey.

Small and strong Pyramid Camellias, Gladiolus SEEDLINGS, per 1000.

LÉVÉQUE ET FILS, NURSERYMEN, 26, Rue du Liégar, Ivry-sur-Seine, near Paris, have small and strong PYRAMID CAMELLIAS, bushy and well formed, from 2s. to 10s., 20s., 50s. and upwards, according to strength and size of plants (alba-plena in quantity).
GLADIOLI SEEDLINGS in all colours, good flowering bulbs, 4s. per 1000.

To Large Planters and the Trade.
LIMES, Red-twigged, from 6 to 7, 7 to 8, 8 to 10, and 10 to 12 feet.
YEWs, English, well furnished, 2½ to 3, 3 to 4, and 4 to 5 feet.
CHESTNUT, Horse, 6 to 12 feet.
LAURELS, 2½ to 3, and 3 to 4 feet.
OAKS, Hedge-row, and Standard ROSES, &c.
Prices and sample dozens on application.
A. GODWIN AND SON, Ashbourne, Derby.

Vines and Strawberries.
"Plant now to ensure a full crop of fruit next season."
FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Canes, 3s. 6d. to 5s. each; strong Fruiting ditto, 7s. 6d. to 10s. 6d. each.
Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Price, in small pots, 10s. to 20s. per 100; from the open ground, 3s. to 5s. per 100.
Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LISTS post-free, on application.
Sheen Nursery, Richmond, Surrey.

Gladioli!—New Roses!—Gladioli!
EUGÈNE VERDIER, Horticulturist, 37, Rue Clisson, Gare d'Ivry, Paris.
New varieties of ROSES obtained in this Establishment, and to be offered for sale for the first time in November:—
HYBRID PERPETUALS.—Charles Ballet, Charles Duval, Comtesse de Flanders, Docteur Auguste Krel, Mdme. Albani, Mdle. Maria Castel, Mdle. Maria Verdier, President Schlechter, Princesse Blanche d'Orléans, Souvenir d'Auguste Rivière.
New varieties of GLADIOLI to be offered for sale for the first time in November:—Caprice, Conquête, Crésus, Eglé, Eugène Ramey, Lactea, La France, La Perle, Leviathan, Madadam Platz, Parmentier, Pasquin, Séduction, Tour du Monde.
New varieties already on sale, magnificent, very recommendable, and much recommended:—Madame Krelage, Lord Hawke, Madame de Cazes, Roi de Jaunes, &c.
CATALOGUES are now ready, and will be sent gratis, on demand, post-paid.

6000—Camellias—6000.
H. WALTON begs to call attention to his extensive collection of the above, of all sizes, from 42s., 63s., 105s., to 120s. per dozen; large handsome plants of all the best varieties, from 21s. to 105s. each, all home grown.
AZALEAS, all the leading varieties in fine healthy plants, from 24s. to 63s. per dozen.
A large quantity of Specimen STOVE and GREENHOUSE PLANTS in fine condition.
ERICAS, in Half and Quarter Specimens, all the best Exhibition varieties.
Inspection invited.
Edge-end Nurseries, Brierfield, near Burnley, Lancashire. See Report, No. 190, page 212, Aug. 18, 1877.

To the Trade.
F. W. COOPER has secured fine pure Stocks of Seed of the following CUCUMBERS, which he can offer at one ounce:—
ROLLISSON'S TELEGRAPH,
TURNER'S BLUE GOWN,
PEARSON'S LONG GUN,
MONRO'S DUKE OF EDINBURGH.
Florist, Huntingdon.

THE NURSERIES, Wandsworth Common, Garratt Lane, and Tooting.
The Nurseries comprise 70 Acres of a remarkably useful and well grown stock of HARDY SHRUBS, FRUIT, FOREST and ORNAMENTAL TREES, CLIMBING PLANTS, &c., especially adapted for planting near London. A personal inspection earnestly solicited. Catalogues free on application to **R. AND G. NEAL**, Chief Office, Wandsworth Common.
The Nurseries are situated one mile from Clapham Junction, on the highroad from Wandsworth to Tooting, and a quarter of a mile from Wandsworth Common Station, London, Brighton, and South Coast Railway.

TO THE TRADE.

JAMES & ROBERT THYNE

are now offering—

- ABUTILONS, in variety, in 3-inch pots, 9s. per dozen.
- ADIANTUM GRACILLIMUM, in 4-inch pots, 9s. to 12s. per dozen.
- ARDISIA CRENULATA, in 3-inch pots, 9s. per dozen.
- ARECA AUREA, in 3-inch pots, 70s. per 100.
- ARECA RUBRA, in 3-inch pots, 70s. per 100.
- CHAMÆROPS EXCELSA, in 3-inch pots, 30s. per 100.
- CICCA DISTICHA, in 4-inch pots, 12s. per dozen.
- CYRTODEIRA FULGIDA, in 3-inch pots, 18s. per dozen.
- COCOS WEDDELLIANA, in thumb pots, 40s. per dozen.
- CROTONS, in variety, in 4-inch pots, 12s. to 18s. per dozen.
- CYATHEA DREGÉI, recently imported and making magnificent heads, 6 feet stems, 12 guineas each; 5 feet stems, 10 guineas each; 3 feet 6 inches stems, 8 guineas each; 2 feet stems, 6 guineas each.
- CYPERUS LAXUS, in 4-inch pots, 6s. per dozen.
- DIEFFENBACHIAS, in variety, in 4-inch pots, 18s. per doz.
- DRACÆNAS, in variety, in 4-inch pots, 100s. per 100.
- IXORAS, in variety, in 3-inch pots, 22s. per dozen.
- LOMARIA DALGAIKINSÆ, 10s. 6d. to 21s. each.
- PAULINIA THALICTRIFOLIA, in 3-inch pots, 12s. per doz.
- PHENIX RECLINATA, in 3-inch pots, 40s. per 100.
- " TENUIS, in 3-inch pots, 30s. per 100.
- PILEA MUSCOSA, in 3-inch pots, 6s. per dozen.
- POINSETTIA PULCHERRIMA, in 5-inch pots, 9s. to 12s. per dozen.
- SEAFORTHIA ELEGANS, in 3-inch pots, 50s. per 100.
- SONERILLA HENDERSONI, in 4-inch pots, 18s. per doz.
- TACSONIA VAN VOLXEMII, in 5-inch pots, 6s. per dozen.

THE QUEEN'S SEEDSMEN, READING.

SATURDAY, NOVEMBER 3, 1877.

RENOVATING OLD FRUIT TREES.

THERE are few fruit cultivators even with only a very limited number of trees who do not at some time or other find a portion of them get into a barren or otherwise unsatisfactory condition. Such a state of things may arise from various causes, such as unsuitableness of soil, want of drainage, or from water being carried too rapidly away through having a loose gravelly bottom. A subsoil of this kind is no doubt well adapted for growing most of the stone fruits, but it would be starvation to Pears and Apples, both of which require a good holding loam, and the deeper this is the more healthy and lasting will they be.

The quantity and quality of the food, and the way it is assimilated, has probably as much to do with disease in the vegetable world as it has in the animal, and when trees are inclined to a mossy, stunted growth or to over-luxuriance, the cause lies beneath the soil, unless it has been brought about by heavy cropping or bad management, such as injudicious pruning or thinning. Crude watery shoots, like obesity in ourselves, is by no means a sign of health, but that the trees are living too fast and doing the work in one year that should be extended over two or three. Wood so formed rarely attains that degree of solidity and ripeness necessary to build up a durable healthy plant, or one that will fruit freely in a climate like that of most parts of England. This objectionable plethoric habit, if not to be traced to the want of drainage, most frequently results from the land at the time of planting having been heavily manured—a practice that prevails to a great extent and often causes much mischief.

If the nature of the ground is such as to require manure it should be given as a surface dressing by way of mulching, and never incorporated with it, as then it does not come in contact with the roots, and can be added or withdrawn at pleasure according to the season and the kind of crop the trees may be carrying. Where it can be had without much labour, sewage is unquestionably the best form of stimulant to apply to all fruit trees, and more particularly to Pears, which when swelling a crop in dry seasons will take almost unlimited supplies. It is astonishing how fertile they become when so treated, over what they are if allowed to depend for the supply of moisture they receive on what falls from the heavens, as then they have as much as they can possibly do to finish and perfect their fruit, and are quite unable to form flower-buds for another year. This is why it is that trees bearing a good crop one season have few or none the next, whereas were they assisted they would bear regularly, unless, as is the case this year, spring frosts destroy the blossoms. Not only does sewage aid fertility, when applied at the proper time, but it likewise improves the size and quality of the fruit; for, as is well known by those who have to do with them, if Pears receive a check while swelling they invariably become hard and gritty, and never finish with that rich buttery flesh and full juicy flavour that all possess, more or less, according to their several varieties, when they ripen off properly.

Although over-robustness in fruit trees is to be avoided, by not using solid manure at the

time of planting, poverty on the other hand is as much to be guarded against, as contraction of the bark immediately follows, or, what is equally as bad, moss forms on the branches, and it is just as necessary to have these free from all parasitic growth as it is that our skins should be clean and healthy if we wish to attain to old age. This being the case, any that are found to be infested with lichen or other conferva should be seen to at once, and the best way to get these eradicated is to scrape the main stem with some blunt iron instrument, such as a small hoe that has been in use some time and has become worn, as then there will be no danger of lacerating the bark. The mossy growth having been removed in this way, together with the more rugged portion of the bark, the next thing is to give a good coat of lime, applied hot and in a liquid state, of the consistency of whitewash. This may be put on with a large brush, and will effectually settle any insects, such as scale or American blight, the latter of which is often most troublesome in old Apple orchards. The branches and twiggy part of the trees may easily be dealt with by using the garden engine or syringe to squirt on the wash, but in order to get it through the tubes of either of these it must first be strained through a fine sieve, to take out any small lumps that remain unslaked and that would be liable to block the passage. The best time to use this lime dressing is when the bark of the trees is just moist from a heavy night dew, as then it sticks and covers more readily than when they are dried by sun and wind; a still fine day is necessary for the operation, otherwise the stream of liquid lime would be diverted from its course, and the work take at least double the time to accomplish. A handy man, expert in the use of either of the above tools, will go over a great number of trees in a day, and a coating of lime will not only be the means of effectually cleaning them, and making their bark bright and healthy, but will keep off birds, which are so destructive to the buds of Plums, Damsons, and bush fruit, so that it is often worth while using it for that purpose alone. The requisite pruning or thinning should of course precede the application of the lime, to avoid handling the branches afterwards, which would not only be an unpleasant task, but would scale off a great portion of it.

In cases where soil is unsuitable from being too light it is surprising what an invigorating effect clay has if trenched in and well mixed as the operation proceeds. I have a quantity of Pears now on the Quince stock that used to flag during dry weather and never bore a fruit worth eating, but since they have been treated to some clay and syringed with lime, they have improved wonderfully, and are now all that can be desired. The trenching was carried out to the depth of nearly a yard, in doing which we worked round the trees, and left them standing on a good sized base of soil to avoid disturbing them too much, as would have been the case had we removed all from under them. The job may appear a heavy one, but then the trees were useless in the state they were, and the improvement has been such that they will now last a lifetime, and amply repay for the labour bestowed on them. The staple of the soil too has benefited in such a manner that it will now grow anything, and will require nothing more done to it beyond a mulching the trees get during the summer, and, when time can be spared, a soaking of sewage in addition.

In regard to old trees whose branches are cankered and hide-bound, beheading them, in addition to the above remedial measures, is the best course to pursue, as they then make shoots free from the former defects, and that soon come into bearing. Spurious or unsatisfactory kinds may be treated in the same way, and grafted when the proper time arrives, as with Apples

or Pears it matters little whether the branches are small if the scions are put in under the rind or worked in other ways, as the circumstances of the case may require. There appears such an amount of vitality in old trees that when beheaded and regrafted they appear to take a fresh lease of life, and soon again become healthy and vigorous, and to all appearance rejuvenated. To destroy such and get up young ones to replace them would be a work of time, and, besides the interest attaching to old favourites, it is therefore desirable to keep them as long as possible. As regards young fruit trees that are over luxuriant and make too much wood, corrective measures must be applied at the roots, as it is useless to attack the tops if the feeding power is not restricted, for the removal of one strong branch only makes room for more of the same kind to follow.

In carrying out such an important work as root-pruning it is necessary that it should be performed by some one who has been accustomed to it, or who possesses the requisite amount of intelligence to do it in a proper manner. Root pruning and root mutilation are two very different things, the one bearing comparison to a skilful surgical operation, while the other is nothing but hacking and hewing at every part that comes in the way. The right course to pursue is to open a wide trench round the plant to be treated, in doing which all fibrous roots should be carefully preserved, and any that are thong-like severed with a sharp knife, as these are the offenders that feed low down in the earth, from whence pump up the crude sap which causes rank growth and general unfruitfulness. The distance at which these may be cut from the tree will depend on its age and size, but may be roughly stated at from 2 to 4 feet, and if the plant is large it will be the safest way to work round only a portion of it—say, from a half to three-quarters, and to leave the other part till next autumn or some future time. The filling-in of the trench will afford an opportunity to work in a little fresh and more suitable soil by mixing it up with the other, the whole of which should then be cast in and firmly trodden down, bringing the main roots to a higher level as the operation proceeds. Like transplanting, root-pruning should be done early, as then the trees have time to recover before the drying winds and frosts of winter are upon them; otherwise they get robbed of their sap faster than it can be supplied them, and when spring comes, with its increased demand, even if the few newly-formed fibres could respond, the bark and sap-vessels will have become so contracted from being so long empty that a free circulation to meet the wants of the fast swelling buds would be impossible. Where root-pruning fails in producing satisfactory results is when it is deferred till too late in the season, or is carried out in an unskilful manner, thereby causing such mutilation and so great a check as to derange the health of the tree. Once get them into a fruit-bearing state there is no difficulty in maintaining them in that condition afterwards, as that is Nature's way of correcting over-luxuriance, and all that is necessary in cases where soil is too rich is to aid her in her work. *F. S.*

New Garden Plants.

ONCIDIUM MACULATUM, Lindl. (*O. DONIANUM*, *Rehb. f.*, alias *ODONTOGLOSSUM LINDLEYI*, *Galeotti*; *ONCIDIUM MACULATUM*, Lindl.; *O. LINDLEYI*, Lindl.)

It is a very curious fact that while the grand majority of Orchids are so constant and complete in the shape of the lips that many subdivisions of genera are established on this very character, yet there are a few cases where the same species bear a lip of a shape diverse enough to serve as a point of distinction of groups. Experience alone can guide us, and teaches over and over again that there are no general rules without exceptions. A very interesting plant of this category is

the old *Oncidium maculatum*, Lindl., which is rather scarce now in gardens, though at one time it was much in favour for its wide panicle of green flowers with blackish brown blotches, and its wide pandurate white lip with an apiculus in front and sometimes some purple on the crests, which are of a very lamentable variability. A very good odour was one of the most appreciated virtues of the plant. Now there is a variety with a narrow lip that has a triangular narrow middle lobe. It is highly curious that this variety occurs with great constancy, though it has no higher claim to the rank of a species. I saw it the first time from Mr Pescatore's garden, whither it was sent by my invaluable correspondent, M. Luddemann. I am pleased to see it again from M. Klaboch, who has just gathered it in Guatemala. *H. G. Rehb. f.*

MASDEVALLIA XANTHODACTYLA, n. sp.*

This is once more one of the Roetzian discoveries—I have obtained it from Mr. Sanders at our friend's instigation, and it stands now in flower (middle of October) in the Hamburg Botanic Garden. It is quite like *Masdevallia melanopus*. Its flowers are greenish white, with yellow tails, and there is a similar violet spot at the base of the flower, on both sides of the chin, as I have very often observed in *Masdevallia Davisii*. The lip and column are nicely mottled and marbled with dark brownish violet. There is also a thick knob of that colour at the inferior base of the very elegant petals, which are nicely serrated towards their upper edge, and bear a membranous crest on their inner surface under the middle vein. It is exceedingly well distinguished from *Masdevallia melanopus* by its very long pedicels—far longer than the bracts; by its only one-nerved anterior lacinia of the lip; and by its totally different petals. *H. G. Rehb. f.*

CATASETUM MACROGLOSSUM, n. sp.†

One day an Ecuadorian (I believe a photographer), having watched Mr. Wallis and his friends, Dr. Krause, Messrs. Klaboch, and Mr. Lehmann packing Orchids for Europe, thought he could manage it likewise, sending *epovillias*,† worth their weight in gold. (By a similar mistake I have just at hand a little bill from tropical America of £11 for Orchids, which would have scarcely fetched 11s. at Mr. Stevens' rooms.) Whether he proceeded himself to the woods, or sent peones, I don't know. One day there came a grand cargo, chiefly consisting of *Maxillaria foveata*, *Gongora grossa*, and *Catasetum macroglossum*. If the poor plants fetched so low a price that the freight of sending was not nearly covered, science had indeed the benefit of two new species, which those clever collectors who care for nothing but making money, never would have touched. This one, the *Catasetum macroglossum*, is near *Catasetum serratum* and planicipes, but is immediately distinguishable by the large semicircular internal callus of the lip of the much larger flowers. Their greatest merit is the wonderful variations of colour in the flowers. I have had them ochre coloured, with green sepals and petals, quite light green, dark green, light yellow, dark yellow, and brownish purple. I have seen it rather frequently, first from Messrs. Veitch, at different times from Mr. Day, and then from Sir C. W. Strickland, and various other correspondents since last November. *H. G. Rehb. f.*

HYPOXIS ARNOTTII, Baker, n. sp.‡

A native of the province of Colesberg, Cape Colony, sent by its discoverer, Dr. Arnot, to the Kew collection in 1855, and flowered there June, 1870. It is marked in the section *Euhypoxis* by its small racemose flowers and narrow densely pilose leaves. Its nearest ally is *H. jacquini*, Baker (*H. villosa*, Jacq., Ic. t. 370, non Linn.).

Tuber large, globose, firm, perennial, 3–4 inches in diameter, crowned all over the exposed part of the top with stiff, erect fibres. Leaves 5 or 6, produced, clasping each other and the scapes at the base for a

* *Masdevallia xanthodactyla*, n. sp.—(Aff. *M. melanopoda*, *Rehb. f.*)—Pedicunculo elongato; racemo paucifloro distantifloro secundifloro; bracteis scariosis triangulis univervi ovaria pedicellata longe non aequantibus; ovario brevi triperito, alis crenulatis retis; tubo brevi superne curvato obtusangulo carinato; pone mentum parvum infra contracto; caudis linearibus tubo subaequalibus; tepalibus ligulatis, antice dilatatis serratis apice subretuso emarginatis seu si mavis angulato excisis cum apiculo; basi ima inferne umbonatis; carina membranacea serrulata insiliente; labello trifido; lacinibus lateralibus obtusangulis, lacinia media linearis obtuse univervi ceterum ecallosa; columna apicem versus trilobulo marginata. *H. G. Rehb. f.*

† *Catasetum macroglossum*, n. sp.—(Affine *C. serrato* planicipis.)—Racemo paucifloro; sepalis con tepalibus lateribus oblongo-ligulatis acutis; labello saccato angulato excavato antice trifido; lacinia media triangula lata parva; lacinibus lateralibus semi-oblongis antice minute serrulatis; tumore transverso semicirculari, antice ante laciniam medianam et in lacinias laterales excurrente; columna bicirrhosa.—Ecuador. *H. G. Rehb. f.*

‡ The vernacular expression for bulbs.
§ *Hypoxis Arnottii*, Baker, n. sp.—Tubere magno globose fibris setosis ubique coronato; foliis productis 5–6 linearibus pedalis pilis albidis mollibus ubique vestito; scapo semipetalis acutato dense piloso; floribus 6–8 racemosis, pedicellis brevissimis; bracteis linearibus subulatis; ovario clavato dense piloso; perianthii parvuli segmentis facie luteis dorso viridibus pilosis interioribus oblongis, exterioribus magis lanceolatis genitalibus perianthii limbo subtriplo brevioribus; antheris leviter versatilibus; stylo integro.

couple of inches, a foot long at the flowering time, 3–4 lines broad, erect, falcate, coriaceous, bright green, closely veined, dotted all over with soft spreading or ascending white hairs half a line long. Scapes two to a tuft, half a foot long, slender, arcuate, densely pilose. Flowers 6 or 8 in a raceme, which is dense at the top, but lax in the lower part; erectopatent pedicels $\frac{1}{2}$ – $\frac{1}{4}$ inch long; bracts linear-subulate, densely pilose, $\frac{3}{8}$ – $\frac{1}{2}$ inch long. Ovary clavate, densely pilose, $\frac{1}{4}$ inch long; limb $\frac{3}{8}$ inch long, bright yellow inside, green and pilose on the outside, the outer segments lanceolate, the inner oblong. Stamens about a third as long as the limb; anthers lanceolate, affixed a little above the sagittate base; filaments very short, deltoid. Style entire, $\frac{1}{2}$ inch long, stigmatose in the upper half.

THE BOTANY OF THE ROCKY MOUNTAINS.

In company with Dr. Asa Gray, Professor of Botany of Harvard University, Cambridge, U.S., I availed myself of an oft-repeated invitation to us both from Dr. Hayden, the distinguished chief of the Topographical and Geological Survey of the United States Territories, to join the Survey in Colorado and Utah; this we did with the view of instituting a comparison between the floras of these central and elevated territories and those of other parts of the continent, and thus obtaining some insight into the origin and distribution of the North American flora. In order to comprehend the importance of Colorado and Utah as the basis for such investigations, I should state that they occupy a very central position in the continent, and include a section of the Rocky Mountains about 300 miles long and about as broad, namely, from N. lat. 37° to 41°, and from W. long. 105° to 112°.

The mountain region thus limited consists of extensive and often level floored valleys, sometimes many miles broad, and elevated 4000 to 5000 feet above the sea, called "parks" in local topography, which are interposed between innumerable Rocky Mountain ridges of very various geological age and formation, which often reach 12,000 feet, and sometimes 14,000 feet elevation, the maximum being under 14,500.

Those of the so-called parks which are watered by rivers that flow to the east are continuous with the prairies that lie along the eastern flanks of the Rocky Mountains; those watered by rivers that flow to the west are continuous with the so-called desert or salt regions that lie along the western flanks of the range; but the "divides" between the head waters of the streams that flow either way are often low, and the botanical features of the east and west may hence meet and mix in one park.

Such a section of the Rocky Mountains must hence contain representatives of three very distinct American floras, each characteristic of immense areas of the continent. There are two temperate and two cold or mountain floras, viz: (1) a prairie flora derived from the eastward; (2) a so-called desert and saline flora derived from the west; (3) a sub-alpine; and (4) an alpine flora; the two latter of widely different origin, and in one sense proper to the Rocky Mountain range.

The principal American regions with which the comparison will have first to be instituted are four. Two of these are in a broad sense humid; one, that of the Atlantic coast, and which extends thence west to the Mississippi River, including the forested shores of that river's western affluents; the other that of the Pacific side, from the Sierra Nevada to the western ocean; and two inland, that of the northern part of the continent extending to the Polar regions, and that of the southern part extending through New Mexico to the Cordillera of Mexico proper.

The first and second (Atlantic plus Mississippi and the Pacific) regions are traversed by meridional chains of mountains approximately parallel to the Rocky Mountains, namely, on the Atlantic side by the various systems often included under the general term Appalachian, which extend from Maine to Georgia, and on the Pacific side by the Sierra Nevada, which bounds California on the east. The third and fourth of the regions present a continuation of the Rocky Mountains of Colorado and Utah, flanked for a certain distance by an eastern prairie flora extending from the British possessions to Texas, and a western desert or saline flora, extending from the Snake River to Arizona and Mexico. Thus the Colorado and Utah floras might be expected to contain representatives of all the various vegetations of North America except

the small tropical region of Florida, which is confined to the extreme south-east of the Continent.

The most singular botanical feature of North America is unquestionably the marked contrast between its two humid floras, namely, those of the Atlantic plus Mississippi, and the Pacific one; this has been ably illustrated and discussed by Dr. Gray in various communications to the American Academy of Sciences, and elsewhere, and he has further largely traced the peculiarities of each to their source, thus laying the foundations for all future researches into the botanical geography of North America; but the relations of the dry intermediate region either to these or to the floras of other countries had not been similarly treated, and this we hope that we have now materials for discussing.

Our course and direction in America was directly westward to Colorado, where we followed the eastern flanks of the Rocky Mountains for about 300 miles, that is from Denver in the north, to near the borders of New Mexico, ascending the highest northern and southern peaks, and visiting several intermediate

There we visited three groves of the "big trees" (*Sequoia gigantea*) at the head-waters of Stanislaus and Tuolome Rivers, and the singular Yosemite Valley, whence we descended into the great valley of California, and made for San Francisco.

From the latter place we made excursions first to the old Spanish settlement of Monterey, which is classical ground for the botanist, as being the scene of Menzies' labours during the voyage of our countryman, Captain Vancouver, in 1798 (whose surveys are held in the highest estimation by Professor Davidson and the officers of the Coast Survey of the United States), whom he accompanied as botanist. Then we went northwards along the coast range to Russian River to visit the forests of Redwood (*Sequoia sempervirens*), the only living congener of the "big trees," and almost their rival in bulk and stature. Then to Sacramento, and up the valley of that name for 150 miles to Mount Shasta, a noble forest-clad volcanic cone about 14 400 feet in elevation. Returning thence to Sacramento we took the Union Pacific Railway eastwards, and from the highest station

and (γ) an interposed mountain region with a temperate and sub-alpine flora.

2. The Pacific slope, subdivisible into (α) a very humid cool forest-clad coast range; (β) the great hot drier Californian valley, formed by the San Juan River, flowing to the north, and the Sacramento River flowing to the south, both into the Bay of San Francisco; and (γ) the Sierra Nevada flora, temperate, sub-alpine, and alpine.

3. The Rocky Mountain region (in its widest sense, extending from the Mississippi beyond its forest region to the Sierra Nevada), subdivisible into (α) a prairie flora, (β) a desert or saline flora, (γ) a Rocky Mountain proper flora, temperate, sub-alpine, and alpine.

As above stated, the difference between the floras of the first and second of these regions is specifically and, to a great extent, generically absolute; not a Pine or Oak, Maple, Elm, Plane, or Birch of Eastern America extends to Western, and genera of thirty to fifty species are confined to each. The Rocky Mountain region again, though abundantly distinct from both, has a few elements of the eastern region and still more of the western.

Many interesting facts connected with the origin and distribution of American plants, and the introduction of various types into the three regions, presented themselves to our observation or our minds during our wanderings. Many of these are suggestive of comparative study with the admirable results of Heer's and Lesquereux's investigations into the pliocene and miocene plants of the north temperate and frigid zones, and which had already engaged Dr. Gray's attention, as may be found in his various publications. No less interesting are the traces of the influence of a glacial and a warmer period in directing the course of migration of Arctic forms southward, and Mexican forms northward in the continent, and of the effects of the great body of water that occupied the whole saline region during (as it would appear) a glacial period.

Lastly, curious information was obtained respecting the ages of not only the big trees of California, but of equally aged Pines and Junipers, which are proofs of that duration of existing conditions of climate for which evidence has hitherto been sought rather amongst fossil than amongst living organisms.

I need hardly add that the part I played in the above sketched journey was wholly subordinate to Dr. Gray's, who had previously visited both the Rocky Mountains and California, though not with the same object. But for his unflinching determination that nothing should escape my notice which his knowledge and observant powers could supply, and Dr. Hayden's active co-operation, my own labours would have been of little avail.

Moreover, throughout the expedition we experienced great hospitality, and enjoyed unusual facilities, not only from the staff of the Geological Survey, but from the railway authorities, who franked us across the Continent, and on all the branch lines which we traversed. *Sir J. D. Hooker* in "Natura."

FIG. 109.—AGAVE STRIATA (SEE P. 556.)

parcs and valleys, watered by tributaries of the Arkansas, Platte, Colorado, and Rio Grande. From Denver we proceeded north to Cheyenne in Wyoming, and thence westward by the Central Pacific Railway, across the range to Ogden, and the Great Salt Lake in Utah, which lies on the base of the Wahsatch Mountains, themselves the western escarpment of the Rocky Mountains proper in that latitude. After ascending these we proceeded westward by rail through Utah to Nevada, thus crossing the great dry region that intervenes between the Rocky Mountains and the Sierra Nevada, which is variously known as the Desert, Salt, or Sink region of North America, in accordance with the prevailing features of its several parts. It is elevated 3000 feet to 4000 feet, and traversed by numerous short meridional mountain ridges, often reaching 8000 feet, and rarely 10,000 feet elevation; unlike the Rocky Mountains or over the Sierra Nevada, these present no forest-clad slopes, or even a sub-alpine flora.

From Reno, at the western base of the Sierra Nevada, we proceeded south by Carson City, flanking the Sierra for some 60 miles to Silver Mountain, when we struck westwards, ascending the Sierra, which was crossed obliquely into the Pacific slope,

visited Mount Stanford, on the crest of the Sierra Nevada, and Lake Tahoe, which occupies a basin in the mountains at about 7000 feet elevation, and with which we finished our western journeyings.

In California the Coniferae were a principal study, with a view of unravelling their tangled synonymy and tracing the variations and distribution of these ill-understood trees, which attain their maximum development in number of species and in stature on the Pacific slope of the American continent.

The net result of our joint investigation and of Dr. Gray's previous intimate knowledge of the elements of the American flora is, that the vegetation of the middle latitudes of the continent resolves itself into three principal meridional floras, incomparably more diverse than those presented by any similar meridians in the Old World, being, in fact, as far as the trees, shrubs, and many genera of herbaceous plants are concerned, absolutely distinct. These are the two humid and the dry intermediate regions above indicated.

Each of these, again, is subdivisible into three, as follows:—

1. The Atlantic slope plus Mississippi region, subdivisible into (α) an Atlantic, (β) a Mississippi valley,

A PLEA FOR HERBACEOUS PLANTS.

ONE good of this peculiar season will be, I hope, a more rapid appreciation of herbaceous plants, and that they may have justice done them, and a fair trial given them in the parks, for it is there that new fashions are seen and make their way. It is all very well to be advised to look through the hardy borders at Kew, Chiswick, and Regent's Park, but no one would be attracted by any such examination—rather, in fact, repelled from attempting to grow such a class of plants. Botanic collections must have all good, bad, and indifferent species and varieties massed together in the most untaking although convenient fashion for such gardens; but exhausted soil, and existing, not happy plants (as is the case particularly where the collections are in beds on grass), will never popularise herbaceous plants. There must be a portion of the time spent on them which is at present wasted over the very artificial carpet bedding now so much the rage, and which I hold a true lover of plants must consider but one step above the coloured glass and stone beds of a few years past.

In public parks all fashions, I suppose, are necessary, as all varieties of taste have to be gratified. Each style is sure to please some who can never enjoy a garden of their own, and it is well to have specimens

and the very best examples of carpet and tropical flower and foliage bedding. But why should herbaceous plants not be represented, also beds of hardy Heaths? No weather would destroy these; no month in the twelve would be without a certain amount of flower. The expense and time at first spent on these two classes of plants ought to be sufficient for many years, if the borders and beds are thoroughly prepared, and there be no stinting of suitable soil and the working thereof, without which the beds would be a failure.

I saw a far greater variety of herbaceous plants at Parker's and Ware's, and more attractively grown, than at all the three botanical and horticultural gardens put together. Surely Kew might set the example of a thoroughly good, and, therefore, taking set of herbaceous and Heath beds, or alternate with such excellent beds of Heliotrope (and other sweet-smelling plants) as are there this season. The perfume was delicious from each side as one walked along. Any provincial attempts that I have happened to see of the newest carpet-bedding have been caricatures of the perfection of the same at Clapham, Victoria Park, and Battersea; and the same remark holds good with the tropical style.

I was not surprised, and was glad to hear from Mr. Legg, the inventor of this ultra-artificial style—artistic I believe is the technical word proper to use—that he had to plant with his own hands all the little mounds, and could entrust such portions of his plans to no one. I was not surprised, because such correctness of eye is perhaps one of the rarest gifts one meets with in gardeners; and I was glad because such a style will never instruct and elevate the lover of plants, it is so utterly artificial, and Nature is tortured and mutilated at every turn. All Mr. Legg's perfection of execution is required to make it attractive, and the time and labour lavished seems something frightful. However, one is independent of sun, and rain improves such beds; possibly, too, the eye may be trained to a greater degree of correctness. It struck me this style looked best by gravel walks. The quantity of green groundwork used is to a certain extent lost when the beds are on turf, and the constant manipulation required to pinch off every attempt at flower or ambitious leaf is apt to destroy the turf around the beds. No beauty of beds can make up for imperfection of the turf.

To come back to a trial of herbaceous plants, it has always struck me in a mixed bed or border seasons should be considered even before heights and colours. Thus summer and autumn flowering plants should be alternate, that there be not a blank in the group or line, and between each strictly herbaceous plant there should be a permanent plant of interesting habit or foliage, coniferous or evergreen, perhaps, any way one not dependent on weather or flowering; and in the back rows such subjects as Acers of sorts, cut-leaved and purple Birches, Oak and Hazel, gold-leaved Catalpas and Elders, the finer and small-growing variegated Elms, Willows, and such small trees whose weeping or peculiar growth of spray would come out against the evergreen wall or background with interest when the leaves drop.

There is a great and distinct beauty in a mixture of deciduous and evergreen growths, each lightens up the other, whether in summer or winter. Then pillars of Roses, Clematis, Honeysuckles, Ivies, Cotoneasters of sorts (beautiful both when in flower or fruit), all firmly supported, but not tied and trimmed up like a Maypole; and Hollyhocks, not in stiff rows, but grown in half circles of five, seven, or nine plants, colours properly arranged, as I have seen at Drummond Castle (Perthshire), the effect of which is excellent; grand curves they made into the border.

With Delphiniums, Aconites, Irises, and Campanulas there would be no want of blue of all heights for summer, and in autumn there are other Aconites, Asters, and Salvias. Red and pink can be dispensed with until the great Poppies, Pæonies, Lychnis, and, of course, Roses (of all heights) come on, as with a choice and plentiful background of early flowering shrubs there would be abundance of red, white, yellow, and lilac—in fact every colour save blue. Early Tritomas, Lilies and Ceanothus succeed, and in autumn there is abundance of all colours and heights. Lists of varied and suitable plants are easily made out, and the placing of such, but selection is necessary, and to keep always in view that herbaceous borders are not torn up at the first frost, but will continue

saving time and labour, and increasing in beauty, season after season.

I am quite sure such mixed borders would be both instructive and attractive, and when imitated (as all beds and borders are) would create, and in many cases revive, a wholesome taste for hardy plants. The variety might be endless, and the plan, although systematic, and to a certain extent regular, could never be caught hold of like a ribbon border—duplicates when repeated being at long intervals.

This is merely a rough sketch, but I hope it may be worked out by some one in some place where many will see, and be converted to what is called old fashioned borders. F. J. Hope, Wardie Lodge.

NEW PLANTS CERTIFICATED

AT THE ROYAL BOTANIC SOCIETY'S EXHIBITIONS, 1877.

PRINCE'S PARK, LIVERPOOL.

(Concluded from p. 525.)

THE best view of the flower ground is from an elevated seat of rockwork situated on an island in the lake, which is spanned by a curiously constructed Chinese bridge, which spans the lake at one point of the island. Of the island itself, we may say that it is in true character with its situation, and contains some curiosities of note, amongst which may be mentioned a singular form of weeping Elm which overhangs the lake. This "curiosity"—for such it really is—seems in excellent health; its form is that of an expanded umbrella, but its freaks of growth are singular in the extreme; it warps its branches in every inconceivable way, but the external shape is neatness to a degree—one leaf laps over another as if they had been placed there by some artificial process. The internal appearance gives one the idea of some aberration of Nature, of which I suppose there are not a few instances in vegetable history. Whatever may be the cause the effect is, as we have stated, a "curiosity," and it is no doubt admired by many a visitor to the gardens. The main attraction within the private grounds is of course the flower garden, laid out in grass, and a smaller one of surpassing beauty which is planted in what is known as "carpet bedding," but mixed beds of old favourites and trees and shrubs are also well cared for. Conifers, except the Austrian Pine, will not thrive here, and needless attempts in a hopeless case are not persevered in. There are from seventy to eighty of the newer varieties of hybrid Rhododendrons, and many large specimens of older sorts. To this tribe of plants much care and attention is given, useless varieties being assigned to some out-of-the-way place, and newer varieties as they are nursed up and furnished filling their places. Paul's double scarlet Thorns are amongst the finest samples we have seen, and are in vigorous health. Male and female Aucubas in large plants occupy sheltered places, and in ordinary seasons do well, but this year they are minus their usual crop of berries.

One or two large specimens of Hodgios' Hollies are worthy of notice for the effect they produce in close proximity to a summer-house; here also may be seen the comparatively new Virginian creeper, Ampelopsis Veitchii, which is self-supporting, requires no nailing, and when better known will doubtless become a general favourite. Adjoining this summer-house is a beautiful arch covered on one side with Laburnums, and on the other with Clematis verticillata. Circular dots here and there are observed, with a Clematis running up a rustic stick, and having a base of Phlox Drummondii. Whole beds of Fuchsia of the gracilis type are charming for autumn effect, and make good relief beds.

On a sloping bank between clumps of Rhododendrons, by way of variety, are beds of Clematis rubella, edged with variegated Ivy; four circular beds of Clematis Jackmanni, edged with Euonymus radicans variegata are of pleasing and graceful appearance, and are a good change where there is plenty of room for variety. We also notice four beds of Fuchsias, varieties of gracilis, edged with a miscellaneous lot of herbaceous plants which are quite at home in the spot selected for them and are an agreeable change from other arrangements.

A stray scroll on a sloping bank is a novelty in itself from the fact of its being planted with Miss Kingsbury Pelargonium and Verbena venosa, edged with English Oak raised by planting the acorns round the margin of the bed—a novel mode of planting, and curious if not interesting.

Coming to the larger of the two flower gardens from the Liverpool side, we find it occupies a narrow stretch of land which is on a raised slope and debouches from the lake beneath; both ends run out to narrow points, and of course the design is worked out accordingly. In a literal sense, or rather looked upon as a plan, this garden is divided into three sections, the centre forming a large circle which is cut out in appropriate design of flower-beds, both ends running into points almost Pear-shape. There is a relief bed of shrubs in the centre of each section, and four large beds, mainly consisting of shrubs, fill up the intervening spaces between the different sections and run to points in the form of a triangle opposite each other on either side.

To particularise the entire bedding of this garden would be a work of considerable length, so that our remarks must be confined to those arrangements that

were thought most striking at the time of our visit, which was when the garden was at its best.

The first bed is of triangular shape, and is planted with Abutilon Thomsoni, Dell's Beet, Centaurea ragusina, Iresine Lindenii, Mesembryanthemum cordifolium variegatum, and Echeveria secunda glauca. A circle of Lancashire Witch Pelargonium and Viola Blue Bell is also a good arrangement, but to our mind the four mixed beds are the most subdued in tone and are altogether a happy combination of colours; they are planted as follows—the centres with Perilla and Abutilons, then scarlet and white Pelargoniums mixed, Beet and yellow dwarf double Tagetes, seallet Pelargoniums, and Dactylis glomerata variegata. An oval bed of Miss Kingsbury Pelargonium, edged with a seedling Lobelia speciosa nana, raised by Mr. Mason, is another agreeable arrangement, and is worthy of recognition as a showy bed. A relief bed in the centre of this plot is planted with variegated Hollies, Thujas, hardy Heaths, Euonymus, Daphnes, Gladioli, &c., and finished off with a miscellaneous edging of dwarf bedding plants.

Another very effective combination of colours is worked out on a large scale, and is a simple groundwork of Lobelia edged with Golden Feather, with dots of Centaurea and Beet, Chamæpuce diacantha, and variegated Pelargoniums; this is one of the grandest beds in the garden.

Oblong beds of scarlet Pelargonium, Aigburth Beauty, with Virgo Marie, with Blue Bell Viola and Golden Superb Nosegay Pelargonium, are very telling; and so are circles of Happy Thought Pelargonium and dwarf Ageratums. Small beds of Sophie Dumaresque and seedling Lobelias go well together, the former growing freely and fine in colour. Double Tagetes, with Lancashire Witch Pelargonium, followed with dwarf dark Violas, and edged with Cerastium, answer well in rotation; and a similar good effect is observable in another bed of Cleopatra Pelargonium, with Viola cornuta Perfection, Little David Pelargonium, and Pyrethrum aureum; whilst Viola Blue Perfection, Pyrethrum Violet Hill, with Centaurea candidissima and Little David Pelargonium, are nothing behind. Beds with the centre and edge of corresponding colours go well, as, for instance, Abutilon Thomsoni, Pelargonium Lancashire Witch, Viola Blue Bell, edged with Golden Feather. Another exceedingly sprightly bed is of Miss Kingsbury Pelargonium, with dots of Verbena venosa, and band of dark Beet edged with Crystal Palace Gem Pelargonium.

Three mixed beds of Canosa and Artemisia argentea, with a groundwork of Lobelias, are prominent and changing features, and occupy important places in the garden when viewed as a whole.

Dark Beet, with double Tagetes, Little David Pelargonium, and Gnaphalium lanatum is very striking; and so is another bed of Bijou Pelargonium, with Blue Perfection Pansy and Pelargonium Memnon, edged with Pelargonium Manglesii. Another form of bedding, all in Pelargoniums, is worked out with Cleopatra as a centre, with band of Virgo Marie edged with Little David. Two large oblong beds planted in design of circles for a centre are planted with Chamæpuce diacantha, dark Violas; next to which is a band of Pyrethrum aureum, with a band all round of Lobelia Blue King, filling in the points between the circles with Mesembryanthemum cordifolium variegatum, and edged with Echeveria secunda glauca.

A match bed to this again, in design of circles, is of Dickson's Beet, Crimson King Verbenas, white Lobelia Purity, Lobelia speciosa nana, Golden Feather, and Echeveria secunda glauca. Mass beds in circles to match are done with Jean Sisley, Königa variegata, with a couple of stray dots of Yucca gloriosa as relieving objects.

We now come to the garden which is set apart for "carpet hedging," and which is the fascinating element of Prince's Park. From various points of the island previously mentioned this garden can be seen in its entirety and in its best dress.

The garden, which is semicircular in shape, is quietly ensconced in a sheltered nook which renders it all the better adapted for the style of bedding to which it is so judiciously set apart by Mr. Mason. The background is composed of a healthy mass of beautiful evergreen shrubs in neat order. On the front it is bounded by the splendid winding lake, with its waterfowl from various climes, its dots of Lilies, and its numerous other attractions.

The planting of this garden is of an artistic description, the plants being selected with due regard to soil and climate, and the arrangements throughout are

(as might be expected from a manager of such lengthened experience as Mr. Mason) as near perfection as it is possible to get.

It will be evident, from our description of the shape of this garden, that the two extremities run out to triangular points, and the beds are therefore planted to match, two and two alike. The beds have all "raised edges," with the exception of the small circular ones, all the raised edges being neatly planted with Echeverias. The corner or triangular shaped beds are planted to represent each other with Coprosma Baueriana pegged down, Alternanthera spectabilis, Lobelia pumila grandiflora compacta, and Lysimachia aurea—a beautiful golden-leaved plant. Two oblong beds are designed in five circles of Lobelia pumila grandiflora compacta, surrounded by a band of Alternanthera spectabilis, groundwork of Mesembryanthemum cordifolium variegatum, edged with Echeverias. Further on are two more oblongs on the circular line of the half-circle, planted with Bijou Pelargonium; then Viola Blue Perfection and Golden Superb Nosegay Pelargonium, edged with Echeverias. Crystal Palace Gem, with band of Viola Blue Bell and margin of Echeverias, comprise the arrangement of two more; whilst two beds of dwarf striped Petunias, surrounded by Golden Feather and Echeverias, are significant of useful changes being introduced into the carpet system. Two half-moons of Pelargonium Robert Fish are well together, as are two beds of Pelargonium William Sandy edged with Lobelia Blue King. Next we come to two other match beds, planted carpet in design, with dots of tall-growing Lobelias, followed by Alternanthera spectabilis, Achillea umbellata (a beautiful dwarf-foliage plant), Lobelia grandiflora compacta, and Alternanthera amœna, with a margin of Echeverias. Were there a prize to be awarded, we should award the palm to these truly magnificent beds, which are strikingly effective. The key-bed on the front line is planted with Pelargonium Cleopatra, next to which is Centaurea, followed by Iresine Lindenii and Golden Feather, and edged with Echeverias.

In conclusion we may just remark that, under the excellent curatorship of Mr. Mason, Prince's Park is not very likely to fall behind as a public place of interest, where the most fastidious will find ample scope for their tastes, however complex or varied. *Q. H. W.* [By an oversight the name of the donor of this park was printed in our last issue as Richard Vaughan Bates, instead of R. V. Yates. We hasten to make the correction. Eds.]

THE PRINCIPLES OF GARDENING.

AT the annual dinner of the Shropshire Horticultural Society, held at Shrewsbury on Tuesday, October 16, the Earl of Powis, who presided, in proposing the toast of "Prosperity to the Shropshire Horticultural Society," said:—From the earliest ages of the world tribes of the most varied character and different in race have all turned instinctively to the arts connected with the cultivation of the garden and the field as those which called forth the purest instincts in our nature. Whether there are some fixed principles which direct insensibly the imagination to the poetry of our nature, or whether it was the expiring light of primitive revelation and the primitive traditions of Eden, are matters upon which we might speculate and raise ingenious arguments on either side; but the fact is, the bucolic age is, as it has always been, a theme for poets and the ideal of perfection. As time advances, as the human race multiplies, and as cultivation increases, we feel naturally a great interest in everything that relates to the cultivator of the field, perhaps upon the larger scale, and the cultivator of the garden, who is more minute in his processes, for neither can dispense with the services of the other. The jeweller who cuts the diamond into innumerable facets, so as to make it give back the innumerable rays of the sun, cannot afford to look down upon or despise the workers in stone; so the gardener cannot dispense with the field worker. Who gave us the idea of the Corinthian capital, or the Apollo Belvidere? The Corinthian capital owes its existence to the vegetable world—we might say to the gardener, because it was from a plant drooping over some neglected stone that the first Grecian architect derived the idea of that most graceful of all architectural orders. In the cultivation of foliage and the cultivation of wood the gardener and the agriculturist united,

The largeness of the trees and the extent of the forests gave to the gardener's cultivation a breadth and imposing appearance.

The gardeners and the agriculturists sometimes became together great elements of natural prosperity. Take, for instance, the cultivation of Tea. In the early days in which this beverage was known to the Western world, in the days when they were told Queen Anne sometimes took counsel and sometimes took Tea, it was taken as a curiosity and sometimes as a liqueur, and the cultivation was exclusively a monopoly of China. By the aid of the gardener and agriculturist, however, it has now become a large cultivation in India, and formed a considerable base to the country's prosperity. Another plant of a more medical character, the Cinchona, or Peruvian bark, which is such a great necessity to the world generally, is also being largely cultivated in India and with great success. These are plants which it was said could not be naturalised in another country, and would not have been if the science of the gardener had not been supported by the larger labour of the agriculturist. At the present time, in the fertile lands of Sicily there is in cultivation a tree called the Eucalyptus, which provides a most valuable timber, and has most wonderful properties of absorbing by its leaves the malaria and bad humour of the volcanic soil. I am also reminded of the late Lord Palmerston, who took an interest in various sports, and would ride down to the Derby, or go elsewhere, and finish up the day by joining in a debate in the House of Commons. He was distinguished by bringing from some distant parts a strong grass, which he had sown on the sandhills of his Sligo estates, and which prevented the sand being driven by the wind over the good portions of the land, and thus spoiling it. In this case the science of the gardener was added to the cultivation of the farmer.

A gardener must be a chemist and a geologist, he must know something of the soil and how it effects the growth of his flowers. Such a plant as the Hydrangea in England produces a beautiful pink, while in Ireland it gives a blue flower, showing that the absence of lime in the soil affects the colour. He must be an engineer to be able to regulate the heating of the hothouses; he must also be an architect, and have a taste for the picturesque if he is to till the modern garden with taste and delight. What is the most difficult of all, he must have good taste, for here in a rich country, where men's fortunes rapidly accumulate, there must be a certain number of persons whose purses increase more quickly than their taste, but because of this the gardener must not desert the lines of beauty, or be captivated by senseless profusion and extravagance. In all these things the gardener of the present day participates in the general progress of science. Mr. Bright at Manchester the other day, spoke of the advantages which had been derived from the mechanical art as applied to railroads by the aid of steam. In gardens a similar improvement has taken place, mechanical art being brought into use to improve the various processes by which houses are heated. The gardener of the present day has greater advantages than those of the beginning of the present century; the old-fashioned stone flue has been supplanted by steam and hot water, which have now been adopted in most conservatories.

When I spoke of the influence which gardening has over the imagination of man, and particularly of poets, I could not bring an instance where it is more strongly shown than by quoting Milton. He was a Republican in politics, and in religion he belonged to the stern school of Puritans; at the time when religious strife made that school assume its sternest character. Yet he records, with a feeling of delight, old stories connected with gardening, and with the old poets expresses the duty of the gardener in a which any professor of horticulture at the present day might approve of and give to his pupils. He says:—

"To-morrow, ere fresh morning streak the East
With first approach of light, we must be risen,
And at our pleasant labour, to reform
Yon flowery arbours, yonder alleys green

* * * * *
That mock our scant manuring, and require
More hands than ours to lop their wanton growth;
Those blossoms also, and those drooping gums,
That lie bestrewn, unsightly and unsmooth,
Ask riddance if we mean to tread with ease."

And as there is no gardener in existence who does not want just one more man it may console him when he reflects that Milton informs us that Adam in the Garden of Eden felt himself short-handed. In cor-

trolling the bounteous provisions of Nature's gifts and colours, the workers in the gardens of the tropics have as much labour as is given their brethren who toil amongst the deciduous foliage of the gardens in Northern climes. There are many romances connected with gardens. We all remember reading how Proserpine herself cut the Crocus, and was carried off to the infernal regions by rather an ardent suitor. But amidst all the changes since the days of mythology there are still garden parties in which ladies achieve their triumphs, but in a milder manner, for you cannot suppose that they would accept violence from their ardent suitors of the nineteenth century. Among the teeming populations of our great towns the formation of ornamental parks is a great source of enjoyment to all working classes. The amateur of the town who looks to his garden gets an hour of exercise, and is enabled to free his constitution from the depressing influences and close atmosphere of the confined room in which he works.

THE GENUS AGAVE.

(Continued from p. 490.)

SERIES I.—CORIACEO-CARNOSÆ.—Texture of the leaf rigid, not fleshy, nor yielding to the touch when mature. End-spine large, hard and pungent.

Group VI. Striatæ.—Edge of the leaf without any distinct border, only minutely serrulate or subentire.

* Surface of the leaf strongly, closely ribbed; edge serrulate.

56. *A. (Littsea) striata*, Zuccarini; Kunth, Enum., vol. v., p. 832; Hook. in Bot. Mag., t. 4950; Jacobi, Monogr., p. 154, fig. 109, p. 553.—Acaulescent, or shortly caulescent; leaves 150—200 in a dense rosette, linear-ensiform, 2—2½ feet long, ½—¾ inch broad above the deltoid dilated base, where they are ¾ inch thick and 1 inch broad, narrowed gradually from the top of the base to the point, rigid in texture, not at all falcate in the typical form, glaucous-green, ⅓ inch thick in the centre, the face rather keeled and the back more so, the point brown and pungent,

Var. 1. *A. recurva*, Zuccarini; Kunth, Enum., vol. v., p. 832; Jacobi, Monogr. 158, fig. 110.—Leaves longer than in the type, reaching 3—4 feet, and more or less falcate, narrower (½—¾ inch broad at the middle) and decidedly convex on both surfaces.

Var. 2. *A. stricta*, Salm-Dyck; Jacobi, Monogr., p. 153; *A. hystrix*, Hort.—Leaves about 1 foot long, very stiff, ¼ inch broad at the middle, both faces convex.

Of this the inflorescence is described by Jacobi (*Nachtrage*, ii., p. 86), from a plant that flowered in 1869 in the Botanical Garden at Darmstadt. It also flowered with Mr. Saunders about 1870, and a coloured drawing was made of this plant, which has not yet been published. The inflorescence quite agrees with that of the typical *striata*.

Var. 3. *A. echinoides*, Jacobi, *Nachtrage*, i., p. 48; *A. ensiformis*, Hort. Engl.—Still dwarfier and stiffer in habit than in var. *stricta*, the leaves about half a foot long, ½ inch broad at the middle, flat on the face.

FIG 110.—AGAVE STRIATA VAR. RECURVA.

Those who see in the east of London the pretty plants brought forward by them to compete for prizes at the garden societies' exhibitions, or see the flowers which the Duke of Westminster gathers around him from the school children of St. George's, can feel what a great deal of good this pursuit creates. Neatness and habits of cleanliness are inculcated by the simple knowledge of the cultivation of flowers. I have spoken of principles which ought to direct the gardener. I think he should not endeavour to tie Nature down to any strict formal rule, but accommodate his designs and the various styles to the country in which he is working. A style which may be suitable in a suburban garden at Twickenham, would be out of place on the rocks of Wales, or the undulating woodlands of Shropshire and Herefordshire, and it is by adapting himself to the beauties of the natural features of the district in which he works, and not by forming incongruous designs, however ingenious, that he achieves triumphs in landscape gardening. I again refer to Milton, who says:—

Let Nature here
Wanton as in ber prime, and play at will
Her virgin fancies, pouring forth more sweet,
Wild above rule or art, enormous bliss.

½ inch long, the edges minutely serrulate, the surfaces marked with close, distinct vertical ribs. Scape 6—8 feet high, including the inflorescence, furnished with numerous spreading subulate bracts, which are 2—3 inches long. Spike dense, 2—3 feet long; bracts linear from a broad base, shorter than the flowers; pedicels very short. Perianth, including the ovary, 1—1½ inch long; ovary oblong-trigonal, about ½ inch long; segments oblong, brownish-green outside, yellow inside, about equalling in length the broadly funnel-shaped tube. Filaments 1½ inch long, dark brown, inserted low down in the tube; anthers ¾—½ inch long. Style reaching nearly to the top of the filaments.

A native of Mexico, now common in our collections. One of the most distinct and best known species. There is a full account and a coloured figure of the plant in the *Botanical Magazine*, as above cited, from a specimen from Real del Monte that flowered at Kew in 1856. I have a photograph of a plant that flowered in October, 1876, with Signor Fenzi at Florence. There are several well-marked varieties, of which the following are the most striking.

A plant I have seen in the Peacock collection under the name of *A. Richardsii*, comes very near the last. There are good typical specimens of all the four forms in the Succulent-house at Kew at the present time.

57. *A. (Littsea) californica*, Jacobi, *Nachtrage*, p. 47; *A. falcata*, Engelm. Notes, p. 16.—Acaulescent. Leaves 20—30 in a rosette, linear-ensiform, 1—1½ foot long, 4—6 lines broad above the dilated base, narrowed gradually to a short pungent point, rigidly coriaceous, flexible, glaucous, falcate, distinctly striated, flat or slightly channelled down the face, the back keeled, the edge minutely serrulate. Scape 3—8 feet long; bracts dry, filiform. Flowers in a dense spike; pedicels very short. Perianth, including the ovary, 1—1¼ inch long; ovary and oblong segments each ½—¾ inch long; tube broadly funnel-shaped, ½ inch long. Filaments inserted at the middle of the tube, exerted about 1 inch beyond the segments; anthers above ½ inch long.

Gathered near Saltillo and Buen Vista in North Mexico by Drs. Wislizenus and Gregg in 1846—1848. The two plants named by Jacobi and Engelmann are evidently the same. My description of the leaves

is taken from the Kew plant, and of the inflorescence entirely from Dr. Engelmann. It is still rare in cultivation, and has not been known to flower. Its only close alliance is with *A. striata*.

58. *A. (Littea) dasyliroides*, Jacobi and Bouché, Monogr., 150; Hook. in Bot. Mag., t. 5716; (fig. 111); *A. dealbata*, Lemaire; Jacobi, Monogr., p. 152.—Acaulescent. Leaves 80—100 in a dense rosette, linear-ensiform, 1½—3 feet long, ¾—1 inch broad above the

1½ inch long, inserted near the throat of the tube; anthers ½—¾ inch long.

A native of Mexico, introduced about 1860, and now widely spread in cultivation. There is a coloured figure and full description from a specimen that flowered in the Regent's Park in 1868. *A. dealbata* of Lemaire is simply a variety with leaves more glaucous than in the type. It flowered some time ago at Reigate, where a coloured drawing was made. The species is one of

as long as the limb; tube very short, campanulate; segments oblong. Stamens little exerted, inserted low down in the tube; anthers ¾ inch long.

North-west Arizona, between the San Francisco Mountains and Colorado River, at an altitude of 4000 feet; discovered by Dr. J. S. Newberry in March, 1848. Not yet introduced into cultivation, and known to me only through Dr. Engelmann's *Monograph*.

FIG. 111.—AGAVE DASYLIROIDES.

dilated base, where it is ½ inch thick, and 1 inch broad, narrowed gradually from the middle to a short brown pungent point, pale glaucous green, rigidly coriaceous, stiff or in the longer forms falcate, flat on the face, and nearly so on the back; ½ inch thick in the centre, finely striated vertically, the edge minutely denticulate. Scape 6 feet long, densely clothed with spreading subulate bract-leaves, the lower ones 1 foot long. Spike as long as the scape, often decurved; lower bracts much longer than the flowers; pedicels obsolete. Perianth 18—21 lines long, including the ovary; ovary oblong trigonous, ½—¾ inch long; segments oblong, yellow inside, equaling in length the broadly funnel-shaped tube. Filaments

the best marked of the genus, resembling *striata* both in the fine ribbing and minute serrulation of its leaves.

** Surface of the leaf not ribbed; edge not serrulate.

59. *A. (Euagave) Newberryi*, Engelm. Notes, p. 21.—Acaulescent. Leaves ensiform, 7—10 inches long, ¾ inch broad above the dilated base, narrowed gradually from the base, to the point, rigid, entire, the pungent dark brown end-spine ½ inch long. Scape slender, 8 feet long. Panicle narrow, lax, the branchlets 1—3 inches apart, 1—2 inches long, bearing each 2—5 flowers; bracts lanceolate, about ½ inch long. Perianth including the ovary about 1 inch long; ovary

60. *A. Houletii*, Jacobi, Monogr., p. 256.—Acaulescent. Leaves, 30—40 in a rosette, oblanceolate, 12—18 inches long, 2 inches broad at the middle, narrowed to an inch above the dilated base, where it is ½ inch thick, narrowed to a brown pungent point ½ inch long, flat on the face, where it is ¼ inch thick; bright green, not striated, glaucous on the back towards the base, rigid in texture, the edge quite entire. Inflorescence unknown.

History not known. Described by Jacobi in 1865, from the Belgian Gardens. I have seen it in the Reigate and Kew collections, and it is included in Mr.

Saunders' series of photographs. In general habit and leaf-texture it is most like the small forms of *Ixtli*, and should be compared with the variety *Sisalana*. This ends the series of the *Coriaceo-carnosæ*.
Y. G. Baker.

GREENHOUSE HARD-WOODED PLANTS.

THEIR CULTURE AND MANAGEMENT.

ERICAS.—These belong to a very numerous family of evergreen hard-wooded plants, indigenous to the Cape of Good Hope, many of those that have been introduced no doubt being natural hybrids, from the seeds of which have been raised in this country numbers of the finest varieties in cultivation. In fact I know of no plants that have rewarded the patient manipulation of the hybridist better than these: patient, I repeat, for those who essay the raising of new varieties of Heaths need to exercise this virtue to an extent not required by those who confine their operations to plants of a more precocious nature. The most successful raisers of Heaths assert, and I have no doubt correctly, that it takes ten years to raise a variety from seed and propagate stock enough of it for letting out, as the greater portion, especially the hardest-wooded kinds, are slow growers, alike from the seed-pan or the cutting-pot.

As decorative plants Heaths stand second to none in cultivation, although in their individual blossoms they cannot lay claim to the gorgeous character possessed by many plants; but the simple beauty of their flowers, with the profusion in which they are produced, added to their wax-like substance and charming tints—ranging from pearly white all through the shades of blush and pale pink to red and the deepest crimson—render them unsurpassed. Their time of blooming varies in the different kinds so much that by growing even a limited selection they can be had in flower almost the whole year round. Like many other fine families of plants, they have at some times been more fashionable than at others, now and again giving place to things that need less attention and are of quicker growth. Nor is this to be wondered at, for they are by no means the subjects to be taken in hand by inattentive cultivators, or those who attempt to make plants collectively conform to some general course of treatment. Those who undertake to grow Heaths should in all cases realise the fact that they will not submit to a give-and-take sort of treatment, by paying them double attention to-morrow or next week, because their wants were neglected yesterday or the week before. Unless they receive continually the attention they need, it is of no use attempting to grow them. I do not know of any plants better calculated to induce in a young gardener the habits of observation, with continuous care and attention, essential to general success in the pursuit. As I have already intimated, the raising of seedling Heaths is an interesting operation, but, unless in the case of those who are disposed to go into the work in earnest, it is better left undone; and the same applies to raising them from cuttings, which to be successful needs especial care and attention.

In making a selection of young stock to commence with, it is of more than ordinary importance that they should be in a free, healthy condition, as if at all root-bound the chances are that a considerable percentage will die when moved into larger pots. Beginners are frequently tempted to choose plants from the size their heads have attained, rather than from the condition of the roots, which latter is of much more importance, as a comparatively young, small plant that has all along been supplied with enough root-space will quickly outgrow one that is double its size above the soil but cramped for room below. During the autumn up to the close of the year, is the best time to get in the plants, as at this season they are free from soft, young growth, and less likely to suffer from the effects of packing and transit. Another advantage thus gained is that they are in hand sufficiently early to admit of such as require it receiving a shift before the hot weather in spring sets in, which reduces the danger of moving them considerably. The plants thus obtained must be wintered in a cool airy light house or pit; if the latter it should be span-roofed, as the ordinary lean-to structures of this description are rendered too dark by the brickwork, which has a tendency to cause premature destruction of the foliage near the base of the plants, in which case they become much disfigured in addition to the weakening influence it

exerts. Elevate them so that they stand well up to the glass in all stages of their existence. There is a two-fold advantage in this; increased light is secured to all parts of the plants, and a freer circulation of air around them—both of equal importance. A night temperature of from 35° to 40°, with 5° higher in the day, will answer for them. They must on no account ever be kept much above the highest of the above temperatures, or it will excite too much growth at a season when it would be highly injurious. The plants should be examined every other day as to their requirements for water, never giving it until it is needed, or withholding it for a single day after it is wanted, applying as much as will moderately moisten the whole of the soil. Look closely over them at intervals to see that they are free from mildew, to which they are more or less susceptible; and if any trace of the parasite is discovered dust the affected plant over with flowers of sulphur, laying it down on its side to keep the sulphur from getting to the soil, whence if washed down to the roots, as would occur in the operation of watering, it would be highly injurious. Allow it to remain on for a few days, after which wash clean off with the syringe.

I have tried the potting of Heaths at different times of the year, and found early, from the latter end of February to the middle of March, the best time for young stock, and September for older specimens; the hot summer months, when shoot-growth has commenced after flowering (a time often advised for shifting large specimens), is the worst possible season that can be chosen, as then the solar heat is so great that it necessitates the admission of a considerable quantity of air to the house in which they are placed, which quickly dries up the soil so as to make the application of water requisite sooner after potting than it should be given with a view to the well-being of the plants by permitting the roots to heal after the more or less breakage inevitable from moving, even when the operation is performed with the greatest possible care. Moderate shifts are the best for Heaths; young plants, say in 6 or 7 inch pots, will bear a 2-inch move—a little more or a little less according to the free or slow growing nature of the variety.

The soil should consist of good peat, varying according to the requirements of the particular varieties. The freest-growing kinds ought to have it somewhat softer, containing more fibre than the hardest-wooded, slowest-growing sorts; the latter also require more sand mixed with the soil than the stronger growers; and if a sprinkling of crocks, broken to about the size of small horse-beans, are added, these will contribute to keep the soil in a sufficiently open, porous condition. It must be borne in mind that the whole family cannot exist if their roots are placed in material that is at all of a retentive nature; on the contrary, it must be such that the water can pass freely through; and as the plants are never intended, or would bear the shaking out and the soil renewing which is practised with many things of a strong-rooted character, it follows that the material used to grow them in should be such as will maintain its porosity as long as they live, and, as Heaths frequently maintain a healthy vigorous condition for a score of years or more, it will be evident that more than ordinary attention should be paid to the selection and preparation of the soil in which they are grown. With these plants more than most things it is necessary to be careful that the soil is not too wet at the time of potting, as if it contains too much moisture it becomes a compact mass, in which the roots never ramify freely, the result of which is that an unhealthy condition of the plant usually follows.

As has been already intimated, the potting of the young stock should be performed about the beginning of March; see that all that are intended to be removed have the ball of soil in which their roots already exist sufficiently moist, so as to avoid the necessity for giving water after they are potted as long as possible, which will give any roots that are broken or bruised in removing the old crocks from the bottom of the balls time to heal up, as water coming in contact with the injured fibres is very likely to cause them to rot upwards. In this way numbers of Heaths, as well as other tender-rooted plants, are lost. Do not on any account disturb the roots more than is unavoidable; disentangling them from the old ball must on no account be attempted. Drain the pots well, using some of the fibrous pieces of the soil to cover the crocks. *T. Bates, Southgate.*

(To be continued.)

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—Blooming subjects here begin to be scarce, but there are numbers of things that do not come under the denomination of stove plants, which are so far benefited at this time of the year by being subjected to a little warmth, that by being so treated they will flower in a way that goes far to make up for the paucity of flowers from the more legitimate occupants of the stove. *Salvia splendens* is one of those plants that I have found do better with a little more warmth at this season, its always brilliant flowers when so treated being produced of a size and intensity of colour that renders it unsurpassed for use at the present time; it is the most serviceable grown to a medium size by not striking the plants too early in the season, and somewhat limiting, but not starving them as regards pot-room, making up for the less liberty the roots thus have by free applications of manure-water as soon as the flowers begin to show. By bringing the plants on in a little warmth at two or three intervals they will make beautiful decorative subjects for the conservatory, or furnish flowers for cutting. *S. Heerii* is equally useful, and comes in to succeed the above, as with similar treatment it will bloom from the beginning of January all through the winter. If the plants of the last-named have now filled their pots very full of roots it will be an advantage to water them exclusively with weak liquid manure. This, like most of the family, makes such a number of roots that it very soon exhausts the soil, which, when reduced to this condition, if not assisted by liquid stimulants is not able to support the plants either to make their wanted quantity of flower or to maintain the foliage in a healthy state. Roses are held in such general estimation that where there is a demand for large quantities of cut flowers many gardeners are expected to produce them all the year round. Where this is the case it is necessary to grow a sufficient number of the Tea varieties to succeed those which were taken indoors some weeks back with a view to enable them to expand the flowers already set upon them; more should now be taken in and placed in warmth, say in a temperature of about 50° at night. If these have been well cared for through the summer they will now be furnished with a considerable number of strong shoots, which should be slightly, not too much, cut back, removing the thinner, weak shoots altogether. They ought to occupy a house or pit, and be well elevated up to the roof-glass, where they will at once start into growth; the shoots thus produced, if all goes well, will soon show flower, and if the plants are well attended to will keep on giving a succession for a considerable time; the stronger growth they make the larger and finer the flowers they produce will be, to promote which they should be supplied with tepid manure-water from the time they are placed in warmth. Before introducing them to the house it is well to make sure that they are free from either aphides or mildew, for the destruction of which I have found nothing more useful than a solution of Gishurst. If prepared two or three days before it is used it will leave much less sediment on the leaves, in this way not necessitating its being washed off with water, and so its effects are more potent. That most useful and continuous flowering of all Abutilons, *Boule de Neige*, should be grown in considerable quantities everywhere where cut flowers in winter are in demand, as it goes on producing a succession when submitted to a little warmth. Its flowers are alike useful in the choicest bouquet or drooping over the sides of a vase or basket. Of Tree Carnations some should now be placed in a little warmth, and likewise subjected to all the light possible as well as a little more air than the generality of other plants require. It is not much use attempting to grow these Carnations in dark, old-fashioned houses at a long distance from the glass; so treated they may open the strongest buds, but the later successional ones will not come to much. The beautiful *Lasiandra macrantha*, the dwarf variety, will shortly begin to open its flowers, for although by varying its treatment it may be induced to bloom considerably later, still the present seems to be its natural season. A temperature of 50° in the night is sufficient for it. One of the most useful plants for forcing is the common *Laurustinus*. I had a number of small standards of this near upon twenty years ago, which were regularly used every winter for a dozen seasons in succession, at the end of which time their heads were not so large as to be cumbersome. The severe cutting-in they were subjected to, by removing some 3 or 4 inches of the shoots along with the flowers, kept them within reasonable limits as to size. They ultimately occupied 12-inch pots, being partially shaken out and repotted in good soil before turning out in the spring when they had been gradually hardened off after forcing. The flowers are much purer in colour when opened in heat than in those produced in the open air. The first batch of *Poinsettias*, if wanted early in bloom, should now be subjected to a brisk heat. The new double sort will

evidently give a succession. A few plants of *Epiphyllum truncatum* may also with advantage be placed at the warm end of the stove. *T. Baines.*

ORCHIDS.—The remaining section of imported Orchids still to be spoken of, viz., *Odontoglossums*, &c., is one to which probably more have turned their attention and energies than either of the classes that have already been treated of. During the last fifteen years so much has been done in Central America in the searching for, collecting, and despatching home these veritable gems, that one is almost led to wonder whether there can now be anything new to find. Such thoughts, however, need not remain long in one's mind, for however much has been done in the days that are gone by, there can be no doubt that there are tracts rich and expansive still unexplored, and that for reasons known to the collectors there are many districts into which it may have been dangerous to force their way, which ere long perhaps even now will be as free and safe for travel as many of those that have been already laid under contribution for the enriching and adornment of our stoves and Orchid-houses. Since Weir and Blunt first journeyed thitherward what numbers of men have been sent on this errand, some losing their lives in their enthusiastic and intense devotion to their love of Nature, and their desire to behold these beautiful forms in their native habitats! Doubtless in the future men, also, will be found still anxious to proceed into the unknown and bring thence the bright and showy forms which, with those we already possess, may charm all who can see beauty in these interesting and often peculiar developments. It is true that vast numbers of *Odontoglossums*, &c., that were gathered and packed in the beauty and freshness of health, have on being unpacked at their destination presented a totally different appearance, shrivelled leaves, rotted bulbs, a heap of ruin and of loss, to be gazed upon with sadness and regret. Others, however, have arrived in every respect satisfactory, and of these it may be needful to say that when such green, plump and healthy clumps are procurable, they should be obtained in quantity if possible, for then the stage by being set apart for a goodly number can be treated much better than where only a few are at hand. Those, however, who can only obtain the smaller quantities, will do well to go carefully over the plants, cutting away any decayed or rotting portions, pot every piece separately in as small a pot as can conveniently be used, making the plant up almost entirely with small crocks, using just a little moss and peat on the surface, as much as anything to steady the plant; and to stand them altogether on a stage or bed having an ash or sandy bottom; or a little sphagnum moss spread on the stage and pushed in between the pots will answer the purpose better. The object is to keep the plants cool and moist so as not to require very heavy waterings at first, as the nature of the material in the pots would otherwise require. Keep the moss and surroundings very moist, and during the summer season shade from the direct action of the sun; in due time the new breaks will appear and the fresh roots will push away into the soil; gradually the new growths will increase in vigour and then will require regular and plentiful watering at the roots. After the first growth is formed they must be potted into larger pots, when it is again best if they all are stood together, it being so much more handy and better thus to get at them. These for the most part are very impatient of fire-heat, and if received in the spring will require but the least amount; as the summer advances giving none whatever. In the winter the imported pieces are a little more trying to manage, though by no means so difficult as to deter any from getting them and endeavouring to grow them. It is a bad practice to make these up by putting several pieces together, it being almost certain that varieties will differ, for scarcely can two be found exactly alike. Moreover, it may happen that not only varieties but species, differing when in flower as much as *Alexandria* does from *Lindleyanum*, or as *Pescatorei* does from *triumphans*, may be found to have been made up in one pot, which having flowered will compel its being pulled to pieces, very often to the loss of one or more of the plants, or the whole of them may be thrown into a long-enduring state of ill health. *W. Swan, Fallowfield.*

FLOWER GARDEN, ETC.

The rapid advance which the season has lately made reminds one strongly of the near approach of winter, and the necessity for being ready to protect all plants that are not sufficiently hardy to stand severe weather. Where the common Fern is plentiful, secure a good supply, which may be stacked up in any out-of-the-way place where it can be conveniently got at. Whenever sharp weather sets in, it will be found most useful for protecting tender Roses, putting round Pampas-grass or any other plants that may require protection. In wet weather straw hurdles may be made which are useful for covering up *Calceolaria* frames, &c., and if made to project 6 inches or so over the glass it will afford better shelter.

outside of the frames may be banked up with cinder-ashes, broken Fern, or litter of any description, which will secure the plants from severe frost. Turf-pits are easily made, and are useful for storing away hardy plants. As the ground has now had a good soaking of rain, any shrubs or trees in clumps or shrubbery borders that may be growing out of their places will remove better than when the ground was so dry and hard. All ground-work should be pushed forward whenever the weather permits. During inclement weather, when men cannot work out-of-doors, their time may be employed in various useful ways, such as making flower sticks and putting them together in their different sizes, which will save time when these things are required for use. Dahlia roots, if not already secured, may be lifted and stored away for the winter. *Gladiolus* should be lifted as soon as the stems become ripe, and dried in an airy place before being stored. As the leaves are falling rather earlier than usual the lawns will be sooner cleared, but in the meantime it seems endless work to sweep up and in half-an-hour find the surface as untidy as before it was swept; still the grass, where most exposed to view, must be brushed up once a-day, which always gives a clean and fresh appearance for the time being, and lessens the amount of labour which would otherwise be required if this was not attended to. Roll walks on every favourable occasion. Nothing adds more to the appearance of a garden than having the walks as firm and smooth as possible. *T. Blair, Shrubland Park.*

FRUIT HOUSES.

FIGS.—In a former Calendar we advocated the principle of full exposure to the force of natural elements of those trees of this kind of fruit when subject to a process of pot cultivation after they had properly matured the current year's growth. As this particular subject will not endure the effects of severe frost without sustaining injury thereby, the trees should now be removed into a place where its operation will be non-effective until they be required for forcing purposes or otherwise. As a rule, the best way of obtaining a very early crop of Figs is by means of having trees in pots, and the best method of effecting it is under the old-fashioned method of employing a fermenting bed of leaves or other fermenting matter in the house for generating heat for plunging and other purposes. Under such conditions great care is, however, necessary in order not to promote a too rapid development. At the first outset be content with merely standing the pots on the surface of the bed, and as fermentation in it diminishes and the heat subsides the pots may be gradually lowered and be finally plunged when it has receded to about 65°. For a very early crop, the first batch of trees should be gently excited at about the middle of the present month in a temperature of about 50° at night, 55° during daylight, and 5° or 10° when sunny weather occurs, as a considerable amount of moisture will arise from the bed, and that of a most invigorating nature. No fire-heat should be used unless absolutely required, and only a moderate degree of syringing indulged in for the present. In the most forward of other houses the leaves will be falling off fast. If any insect pests abound, the rule of collecting the leaves every day cannot be too strictly enforced. As soon as possible after the leaves are down, proceed with the pruning, cleaning, and dressing of the trees. Giving the utmost diligence to such matters now will more than fully compensate hereafter for the extra time it may take. In the latest house which contains these subjects there will still be fruit ripening—most valuable, too, at this season; and therefore a nice dry, warm, and airy state should, as far as possible, be preserved, using for the object a little fire-heat constantly. *George T. Miles, Wycombe Abbey.*

THE ORCHARD HOUSE.—Under the influence of an exceptionally fine autumn all kinds of orchard-house trees are going to rest well set with blossom-buds on thoroughly ripened wood, conditions which give every promise of fine crops of fruit next season, provided the trees are properly managed through the winter, but it frequently happens that stone fruits are kept too dry at the root when in a dormant state, and as this is the most fertile cause of the buds dropping in the spring, every pot should now be examined, top-dressed, if not already done, and thoroughly soaked with water. They may then be set moderately close together, and well covered up with dry Fern or litter to prevent evaporation and to protect the pots from injury by frost, should the winter prove severe. Let the ventilators be kept wide open by night and by day as long as the weather continues open and mild, and only close them when the temperature falls below freezing. Trees intended for potting should now be lifted from the open ground. Shorten back all strong roots; use clean carefully crocked 10 or 12-inch pots, ram the compost quite firm, and place them in the coolest part of the house, or plunge in a sheltered but open place out-of-doors. Figs in pots which have been carried to a

warm house to finish off the second crop of fruit may, as soon as convenient, be returned to the warmest part of the orchard-house, where, with the protection of dry Fern, they will pass through the sharpest winter uninjured. Stone fruit trees, Pears and Plums growing in the open borders, can only be kept in a fruitful state by following up a regular system of lifting and root-pruning. Have a good supply of pure heavy turfy loam at hand; give each tree a few shovelful to encourage the new roots, water freely, and after a few days level down and tread the surface soil firmly and evenly all over the borders. If mulching is resorted to the materials used should not be too rich. Dry Fern or stable litter best answer the purpose, and stimulants can be given where the trees are under the strain of full crops of fruit. *W. Coleman.*

HARDY FRUIT GARDEN.

Although the weather of late has had a most beneficial effect in ripening up the wood of fruit trees and developing plenty of flower-buds, the effect of the cold ungenial spring and early summer on Apicots, Peaches, and Nectarines is still seen by the crippled state they are in, which, except in the best districts, are so bad, that numbers will have to be replaced. This is a serious matter for many, as it takes years to get others established and in a bearing condition, but if the mischief is to be repaired there is no help for it but to set to work and plant the largest and best that can be got. Under the most favourable conditions Apicots will canker and trees die off, and therefore where there is much wall surface to keep furnished, it is a good plan to have a few reserve plants ready trained to fall back on in case of emergency. This may readily be done by taking advantage of any bare vacant spaces on buildings of any description where the aspect is suitable, or, falling situations of this kind, by tying to stakes in the way they do in the nurseries. By adopting this course much loss of time is spared, as trees may be so manipulated by root-pruning or occasional transplanting to have them bristling with fruit-buds, and if removed early in the autumn they will bear the following year, whereas such as are ordinarily to be had from the growers will not do so under at least two or three. Even if large trees can be purchased, the carriage comes heavy, and the price is proportionate, so that there is much economy in getting them in a small shape and growing them on till required for filling up gaps. Now that the leaves are fast falling, no time should be lost in procuring as many as are likely to be wanted within the next year or two, as not only will it be much better for the welfare of the plants to get them in thus early, but it is generally an understood thing that first-comers get the pick, and the demand during the present season is sure to be great, so that those who send in their orders early will benefit both ways. That there may be no delay when the trees are received in getting them planted those they are intended to replace should be uprooted, suitable soil prepared and got ready to hand on the spot, holes dug, and, where necessary, drained by putting in 6 inches or so of broken bricks, or by running a sunk gutter of the same along the front of the border. In very retentive soils both may be requisite, but it is generally better to plant on slightly raised mounds than to over-drain, and to correct the adhesive nature of the land by working in burnt clay, sand, or any light earth that will improve its texture and friability. The use of leaf-soil or other vegetable matter for such a purpose is one of the greatest mistakes possible, for unless in a very advanced stage of decomposition it is sure, sooner or later, to generate fungus—a parasite which, when once it fastens itself on the roots of plants, completely paralyses their growth, and eventually kills them outright. I have seen repeated instances of this, especially during the last few summers, the exceptional dryness of which has induced a condition in the soil highly favourable to its being generated, and afterwards spreading in a rapid manner. Where land is not naturally favourable there is nothing like good turfy loam for planting trees in, and the fresher this is the better, so long as the herbage has been rotted down, or has been pared off before carting. If a few barrow-loads of such stuff as this are afforded each plant they will start off vigorously, and at some future time more can be added, in which way they get it fresh as their roots spread, and the labour of moving a quantity of soil is extended over a series of years instead of having to be done all at once, which is a great convenience where there is a deficiency of labour. However poor the nature of the loam may be on no account should manure be incorporated with it, and more particularly if used for stone fruits, as it only induces a crude watery growth; and what assistance such trees require can always be afforded them by applying sewage-water or a surface-mulching during the summer when carrying a crop. Indeed the two are at that time necessary, and are important aids to successful fruit culture, the one supplying the requisite food in a form that it can be immediately made use of, and the other imparting shade to the roots and maintaining the soil in a moist healthy condition by intercepting evaporation. *J. Sheppard, Wooler stone Park.*

THE

Gardeners' Chronicle.

SATURDAY, NOVEMBER 3, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Nov. 5	Sale of Dutch Bulbs, at Stevens' Rooms. Royal Horticultural Society's Meeting of the Fruit and Floral Committees, at 11 A.M.; Scientific, at 1 P.M. General meeting at 3 P.M.
TUESDAY,	Nov. 6	Clearance Sale at Fillebrook Nursery, by Frotheroe & Morris (three days).
WEDNESDAY,	Nov. 7	Sale of Hardy Shrubs and Dutch Bulbs, at Stevens' Rooms.
FRIDAY,	Nov. 9	Sale of Trees and Shrubs, at the Southwood Lane Nurseries, Highgate, by Frotheroe & Morris.
SATURDAY,	Nov. 10	Sale of Dutch Bulbs, at Stevens' Rooms.

EVERY gardener is familiar with the white mealy substance in the grain of Wheat, with the white flesh of the Cocoa-nut, and countless similar substances in various seeds. To botanists this substance is from its external resemblance often called the ALBUMEN, but as objections may very fairly be raised to this term, that of perisperm or endosperm is now often used in its stead. The object of this perisperm is very obvious. It is a store-house of nourishment upon which the young seedlings draw before they have acquired the power of feeding for themselves. Hence we often find that in the case of those seedlings which have from the first a well-developed feeding apparatus in the shape of green seed leaves, as in the Turnip or Mustard, the albumen is at the time of germination either non-existent or in very small proportion. On the other hand, where the albumen is abundant, there the seed-leaves or cotyledons are very small and inconspicuous. The difficulty in inducing some seeds to germinate is connected with the fact that the seedling plant is often able to feed upon the albumen, but is not able to shift for itself; hence, when the supply of albumen is exhausted, the seedling fails. This is the secret of the difficulty in getting seedling Cocoa-nuts to grow in this country. They grow for a time—all the time the stores laid up by the mother-plant last; but when these are used up, they seem to have no power to run alone. All this is so well known alike to gardeners and to botanists that we should have hesitated to allude to it but for some very curious experiments which have lately been made M. VAN TIEGHEM, and recorded in a recent number of the *Annales des Sciences Naturelles*. The physiologist just named was anxious to know how the seedling plant got its nourishment from the albumen, and in the course of his experiments ascertained some very curious facts, from which it appears that this albumen in some cases acts as a nursing mother to the young embryo, while in others the young plant merely helps itself to what it finds handy. Albumen of an oily character, such as that of Poppy or Cocoa-nut, undergoes a change of structure and composition—digests itself, in fact, and the young plant does but take up the products of this change in the tissues and constitution of the albumen.

Floury albumen, such as that of the Wheat, is passive. It is changed, and ultimately absorbed and digested by the embryo itself. It is of the nature of food simply, and does not, as in the former case, also fulfil the office of a nursing mother. The germination of seeds, the length of time required for the process, and other matters of much interest to cultivators are thus seen to depend very materially on the nature of the albumen—a fact long suspected, but which has not, so far as we know, previously received so practical an illustration as it has now done in the hands of M. VAN TIEGHEM.

We are happy to be able to announce that Sir JOSEPH HOOKER will favour us with some notes (with illustrations) on his recent journey in Colorado and California, with special refer-

ence to the Conifers of that district which have so much interest for our horticulturists. Sir JOSEPH speaks of forests of Sequoia (Welling-tonia) forty miles in extent, of Junipers vieing in age with the Sequoias and of singular pyramidal form, of trees cut through by natural sand blasts, and of other matters which arouse our interest and excite our curiosity.

— It is a fortunate circumstance that many BOTANIC GARDENS, both at home and abroad, have the advantage of proximity to fine architectural features. This association affords some compensation for the ugly arrangements which are thought, very erroneously, to be absolutely essential in a garden whose main purpose is educational. The Oxford Botanic Garden is a case where the proximity to the beautiful Magdalen tower lends an additional charm. The garden at Padua, illustrated in 1876, vol. vi., p. 686, with the remarkable group of buildings adjacent, afford another example. In our present issue we give a view taken from the BOTANIC GARDEN, PISA, with which we have been favoured by Professor CARNEL (fig. 112). The famous leaning tower of white marble here forms a very striking object. Of the garden itself, rich in interesting plants and noble trees, and well administered in all departments, we need not say anything now, but refer our readers to the account published in our number for August 8, 1874.

— Some time since Mr. ANTHONY WATERER sent us a few leaves of a Vine which we may truly say were magnificent both in size and colour. In size they were as large as the largest dinner-plate and more, in form they were roundish ovate, nearly entire, or with a few minute teeth along the margins. The upper surface was of a rich claret colour, the lower surface covered with reddish felted down. The leaves were so superb in their autumn livery that we lost no time in endeavouring to ascertain to what species they belonged. Mr. WATERER himself could furnish us with no information on the subject. None of the gardeners to whom we showed them recognised them, but in the Kew herbarium, with the assistance of Mr. LE MARCHANT MOORE, we determined them to belong to *Vitis lanata*, a Himalayan species long ago introduced, but which seems to have been neglected in gardens, or, as is most probable, Mr. WATERER has in some way become the fortunate possessor of a very fine variety, for, as is well known, few plants are more variable than Vines. Moreover, it must be remembered that our determination was founded on specimens which, for botanical purposes, were very incomplete. Nevertheless, we have little or no doubt as to the correctness of our identification. In ROYLE'S *Illustrations of the Botany of the Himalayas* is a brief reference to *V. macrophylla* as a most conspicuous form, climbing trees, and hanging down in elegant festoons from their tops. This form, singularly enough, is only thus briefly mentioned, and the name has not been taken up botanically, so far as we can find, either by ROYLE himself or by any subsequent writer on Indian Vines. Professor LAWSON, in his Monograph of Indian Vines in HOOKER'S *Flora of India*, makes no mention of it, but gives the following account of *Vitis lanata*:—"Branches, petioles, and cymes more or less pubescent or tomentose; leaves cordate-ovate or shortly acuminate, membranous; peduncle bearing a simple or branched tendril; petals cohering at the top. *Vitis Labrusca* var. γ Regel; Kumaon, 6000—7000 feet; Kashmir, 1000—4000 feet. A very variable plant in the size, shape, and vestiture of the leaves." It is then, to say the least, probable that ROYLE'S *V. macrophylla* may be intended for our present plant, and that it is a variety of *V. lanata*. Be that as it may, we trust Mr. WATERER will speedily propagate and distribute this noble Vine.

— The twenty-fourth annual general meeting of the SCOTTISH ARBORICULTURAL SOCIETY will, by the permission of the Regius Keeper, be held in the rooms at the Royal Botanic Garden, Inverleith Row, Edinburgh, on Tuesday, November 6, at 11 o'clock—the Right Hon. W. P. ADAM, of Blair Adam, M.P., President, in the chair. The following papers submitted by members will be read:—1. On Schools of Forestry. By Rev. J. CROMBIE BROWN, LL.D. 2. Note on a Liquid for Protecting Young Plantations from Game. By WILLIAM LENNOX, Assistant

Forester, Kelly. The following subjects selected at the last annual meeting will be discussed:—1. Woods for Making Different Kinds of Charcoal, and the Modes of Preparing it. Discussion to be opened by Mr. ROBERT BAXTER, Forester, Dalkeith Park. 2. Cryptogamic Plants Injurious to Forest Trees, and their Remedies. Discussion to be opened by Mr. MALCOLM DUNN, The Palace Gardens, Dalkeith. The anniversary dinner of the Society will take place in Robertson's Albert Hotel, 25, Hanover Street, at 4 o'clock precisely. Dr. CLEGHORN will act as Chairman, and Bailie METHVEN and Mr. WILLIAM M'CORQUODALE as cronpiers.

— Rarely have we seen the MARKET GARDENS OF MIDDLESEX better cropped with winter produce, or that produce looking more favourably, than at present. Breadths of Broccoli, Coleworts, Brussel Sprouts, and Savoys, alternate with winter Ooions, Spinach, Turnips, and other vegetables, and Wallflowers and Violets are blooming early and freely. Already the welcome rains have brightened up the crops, and they have regained that rich green hue so characteristic of the winter greens during a growing autumn. The rains that fell so freely in the summer gave a capital opportunity for the getting out of all kinds of plants, and now the winter green crops are most abundant. Turnips have been and are unusually plentiful. The well-known beetle or fly has had a bad time this season, and in many places has hardly been seen. The excellence of the Turnip crop is also most marked, the roots having grown quickly and yet not with too much luxuriance. Collards are seen in large breadths of tens of thousands, looking as even as if mown with a scythe, a fact that speaks well for the admirable quality of the seed stock from which they are raised. The taste for spring Onions would seem to be growing, as large breadths of these are sown and look just now like broad patches of young grass; growers find it to be of the first moment to have these well hoed and thoroughly cleaned before the winter sets in, otherwise the weeds might soon overgrow the crop. The early flowering of the breadths of Wallflowers is giving some additional work to the labourers, both men and women, and are most welcome to the grower, who has none too much just now that is in active demand; the same might be said of the Violets, all of which are blooming very early and most freely. Lee's Victoria Regina, where grown as a market plant, is giving the greatest satisfaction because of the great size and rich perfume of its flowers. Owing to the unsettled state of trade, and the general comparative emptiness of the fashionable part of the Metropolis, no very large demand for winter green stuff has yet set in, but there will be a call presently, especially if hard weather should ensue. Market growers are not unfeeling, but they will not be sorry if the winter be rather more severe than usual!

— A meeting of the committee of the NATIONAL ROSE SHOW took place recently in the rooms of the Horticultural Club, at which a statement of accounts was submitted, showing a deficiency of something like £57. The sum of £127 remained unpaid to five of the largest prize-takers, and these generously resolved to take only 50 per cent. of the prize money, so that the balance-sheet might be closed after the accounts had been submitted to an auditor. The subscriptions and donations from something like 300 members amounted to £67. It will thus be seen that a National Rose Exhibition, started under the most favourable auspices, and to all appearance supported by the strength of the rosarians, has failed to pay its way. The meeting, which may be said to have fairly represented the National Rose Society, as yet strongly in favour of holding an independent exhibition in London about the last week in June, instead of accepting offers from the Alexandra Palace, Royal Aquarium, or Crystal Palace, and the Agricultural Hall and the Floral Hall were named as offering the necessary accommodations. A sub-committee was appointed to make enquiries as to the fitness of these places, and the terms on which they could be had for the purpose. It was felt by the committee that encouragement should be held out to the Northern growers of Roses in the shape of a Northern show, and a suggestion that it should be held at Preston in connection with the provincial meeting of the Royal Horticultural Society was favourably received. Mr. H. K. MAYOR has ceased to be one of the hon. secretaries of the Society, and the

FIG. 112.—THE BOTANIC GARDEN, PISA, WITH THE LEANING TOWER.

hon. secretaries are now the Revs. H. H. DOMERAIN, J. B. M. CAMM, and Mr. EDWARD MAWLEY, the latter gentleman being a most active and valuable member of the committee.

— In Covent Garden Market a few days since might have been seen dense clusters of some small fruits which in the way exhibited might well puzzle a botanist; closer examination, however, showed that they were the fruits of the WILD SERVICE, *PYRUS TORNINALIS*, strung together so densely as to resemble the dense mass of fruit which some Palms bear. Mr. BERKELEY tells us that in some parts of Northamptonshire the tree is so abundant that the fruits are strung together as we have described, and borne in procession at the village feasts. The fruits should be blotted, like the Medlar. The wood of the tree is hard, and valuable for many ornamental purposes. It is not uncommon in Kent and other counties. It is necessary not to confound these wildings with the true Service tree, *Pyrus* or *Sorbus domestica*, of which a tree did exist some years since in Wyre Forest, and of which an account with illustrations was given in our columns, 1874, vol. i., p. 283. We learn from Toulon that the fruits of the true Service are at the present time largely sold in the markets of that city. The fruit is much larger than that of the common Service, and cannot be mistaken by any one who has ever seen the two. The character of the tree and the foliage are very different in the two cases.

— At this dull time of year, when flowers even in greenhouses are scarce, we may recommend *DISIDIS-CERULEUS* to the notice of our readers. The plant has much the general aspect of our wild blue Scabious, but it is nevertheless an Umbellifer of some interest to botanists as well as to gardeners. Another plant less often seen than its merits warrant is *Gesnera insignis*, a noble-looking species, with hold ovate downy leaves and terminal panicles of large lilac flowers like those of a Foxglove in shape. *IMPATIENS JERDONÆ* is likewise a stove plant, not nearly so much grown as it ought to be; its quaint flowers, with their scarlet and gold livery, are sure to attract attention wherever seen. *Astelia Banksii*, a plant for a cool conservatory or winter garden, with its grassy leaves, elegant habit, and dense inflorescence covered with white down, has the advantage of being almost always in flower. The foregoing plants are at the present time noticeable at Kew.

— Mr. WILLIAM BAILLIE, one of Mr. DUNN'S foremen at Dalkeith, has just left there to succeed Mr. ISAAC MASLIN, as gardener to ROBERT FELLOWES, Esq., Shotesham Park, Norfolk. Mr. BAILLIE is a man of excellent ability, and no doubt will do credit to himself and the place he takes charge of.

— Dr. GEORGE BENNETT, of Sydney, has favoured us with the following notes on the NATIVE POMEGRANATE OF AUSTRALIA (*Capparis Mitchellii*), and the larva of a butterfly (*Pieris teutonia*) which feeds upon it:—During the month of January the native Pomegranate tree (*Capparis Mitchellii*) is seen profusely in flower. It is a tree of moderate size, growing from 10 to 25 feet high, and when in full blossom is of great beauty, the white flowers contrasting with the bright green foliage. The wood is hard and close-grained. It is known in the colony of Queensland as the "Native Pomegranate," and is eaten by the aborigines, who name it "Moquile." It is also found about the Namoi, Liverpool Plains, Upper Darling River, &c., in the northern part of New South Wales, where it is named "Bombal" by the aborigines. A fine specimen of the fruit which I examined was extremely woody, of a dark green colour, and measured 2½ inches in diameter, with a thick and woody pedicle 3½ inches in length. The fruit when ripe has a powerful and agreeable odour, very much resembling the fragrance of the flowers of the *Magnolia fuscata*. In 1869 I for the first time observed that the foliage of this tree, as well as that of another species, *Capparis lasiantha*, both growing in the Botanic Garden at Sydney, New South Wales, were almost destroyed by the larva of a butterfly (*Pieris teutonia*). I observed them in every stage, from the larva to the butterfly. This insect confined its ravages to the *Capparis* only, leaving all other trees in the garden untouched. This continued every subsequent year until in November, 1875, the caterpillars were observed to have commenced to feed upon the foliage, when a man was deputed by the director of the

gardens daily to collect and destroy them, the result of which was that their ravages were arrested, and the trees appeared that year in full foliage and blossom, and in the following year but very few were seen, and soon destroyed.

— M. MARCHAND, writing in the *Bulletin d'Arboriculture*, mentions that the natives of Lower California make use of the *ECHINOCACTI*, which grow in such abundance in the mountains, as food. The plants are thrown into boiling water, by the aid of which the spines are removed, slices of the Cacti are then fried as Aubergines are cooked in Europe, and, thus treated, they constitute, according to M. MARCHAND, a very delicious vegetable.

— One excellent quality of the old favourite *VERBENA VENOSA* is that rabbits will, in general, not touch it. Why do we not more often see this very desirable old plant?

— The *CHRYSANTHEMUMS* IN THE INNER TEMPLE GARDENS are now fast coming to their best, and all who intend seeing them had better pay them a visit during the next fortnight. Mr. NEWTON evidently relies upon old favourites, as there are only three or four new varieties in the collection this year, of which *Gloire de Toulouse*, a bright rose-coloured flower with a white centre, and *Cossack*, a pretty maroon and yellow, are the most noticeable. Among the old ones special mention may be made of *Elaine*, large snow-white; also *James Salter*, a pretty mauve; *Golden Beverley*, fine large flower; *Lord Derby*, a dark purple incurved flower; *Gloria Mundi*, a large golden-yellow flower; *Plenipo*, a rose-purple, with a silvery shade, &c. The gardens will, by the kind permission of the Benchers, be open to the public during the continuance of the show.

— A plant of *DIPLODADENIA BOLIVIENSIS*, trained along the roof of the small span-roofed Orchid-house at Ealing Park, the residence of J. S. BUDGETT, Esq., is now in fine bloom, and flowers with great profusion. The plant is in a pot standing on one of the side beds, and the shoots are carried lengthwise along the roof trained to wires. Mr. EDWARDS, the gardener at Ealing Park, states that he can cut blossoms from it all the year round, but that it is especially valuable at this season of the year, when white flowers are scarce. The blooms show themselves off to excellent advantage when placed on the dining-table in specimen glasses.

— One of the best forms of the IMPROVED *SOLANUMS* can now be seen at Ealing Park. In one house there are about six dozen plants of a singularly compact short-branched habit of growth, and completely laden with large bright coral-red round berries. The peculiarity about the strait is that as the berries colour they appear to thrust themselves outside the leaves, and they are thus fully exposed to view. About a month ago the plants were lifted from the open ground and potted, and they have not lost a leaf by the process. As soon as the berries were set the leading shoots were pinched back. The variety is an invaluable one for decorative purposes at this season of the year, and Mr. EDWARDS is growing a great quantity of it for the purpose.

— *CHRYSANTHEMUMS* generally are blooming very late this season, and it has been found expedient to advance the dates of some of the shows a week or ten days beyond the time originally fixed. The plants were late in getting into growth, and the absence of sun greatly retarded the plants. Some collections have yet a great deal of lee-way to make up, there being scarcely the appearance of a bud approaching the expanded state.

— Of all the *COLCHICUMS*, the double-flowered form of *C. officinale* appears to be the most desirable, as the blossoms are large, fully double, and they remain a considerable time in flower. It is very free of bloom also. Strong bulbs throw up a large quantity of flowers.

— It is interesting to notice how thickly set with berries the COMMON HOLLY appears to be generally. The yellow-berried variety is very fertile of fruit also, and now that the berries are rapidly taking on their colour they are daily becoming more attractive. There should be no lack of berried Holly at

Christmas if what can be seen round London is general throughout the country.

— Many beautiful species and varieties of AUTUMNAL CROCUS are now in flower at Kew. *C. byzantinus* has a nearly blue perianth and is without veins of colour; it is very ornamental, and from its comparatively small inner segments is at once distinct in effect and safe from confusion with others. It has been considered rare, and is often grown as *C. iridiflorus*. The well-known *C. speciosus* is decidedly the most showy of all; its flowers are large, deeply coloured and beautifully veined. Fortunately it grows freely, sometimes being almost a weed, and would certainly be of great value in pots for the conservatory. *C. pulchellus* is nearly allied to this but much smaller, its flowers are pale lilac with beautifully defined veins. *C. longiflorus* and the variety *melitensis* are in flower together, and of the two we much prefer the type which has the larger flowers and deeper colour. The perianth is rosy lilac, presenting with the deep orange-red stigmas a rich glow of colour. *C. Boryi* var. *lævigatus* is pretty and distinct from others in bloom, its flowers are cream coloured with a yellow throat and orange stigmas. Another variety, *C. Orphanidis*, is interesting from its feature of remaining open during the night and dull weather; it is of delicate mauve colour, with white anthers and yellow stigmas. This is extremely rare. The perianth of *C. cancellatus* is pure white with yellow throat, the anthers are yellow, and the stigmas orange-red. It again is somewhat rare, though common in a wild state under several forms. *C. Clusii* has pale lilac flowers with in this case narrow acute segments. There are nice clumps of *C. medius*, a species rare in a wild state, and confined to the north-west of Italy and the adjacent corner of France. The perianth is lilac, with darker lines about the throat. It is ornamented with stigmas much divided, even to the condition almost of a little tassel. *C. serotinus* is a rare and pretty species, with pale lilac flowers, described as having much the appearance of *Colchicum autumnale*. A variety of this, *C. Salzmanni*, also rare, and a native of Tangiers, brought hither in a living state by Sir JOSEPH HOOKER a few years ago, concludes the list of those at the present moment in bloom. *C. nudiflorus* is now over. We are pleased here to note that true *C. sativus*, said by mistake in one of the journals lately to be absent and not known in another botanic garden. It is also grown at Chelsea, and in at least one nursery as *C. saffranus*. These autumnal Croci are worth much more attention than they usually command, and some at least should have glass protection from the inclement weather of the season.

— *CRASSULA RUBICUNDA*, in bloom at Kew, is deserving of mention for its highly ornamental and uncommon character. Several stems proceed from a common base, bearing above a large mass of red flowers similar in effect to *Rochea*. The width across the top is about 1 foot, and the height is a little more. The leaves are narrow, 5 inches long below, passing upwards into the bracts. It makes a good specimen, and has the advantage of flowering with certainty at a season when flowers are scarce. A native of the Cape of Good Hope.

— At AMERICAN WEDDINGS the bride and bridegroom during the ceremony often stand beneath a bell formed of exquisite flowers. The idea is so pretty, says *The Queen*, that a contemporary recommends it to those who may be busy decorating a church or a house on the occasion of a marriage. No expense or trouble is spared, the choicest blooms being used; and these bells cost sometimes as much as £20. In the matter of floral decorations English people are wont to keep much in the same track, and might, if they were so minded, learn many novelties from abroad. In Denmark, for instance, charming oval wreaths are formed of the long fronds of the *Filix-mas* Fern, the points meeting at the top, while the stalks are hidden at the base by flowers of vivid colour, contrasting well with the green leaves which seem to spring from them. The oval wreaths are generally about 10 inches high.

— At a recent meeting of the Paris Academy of Sciences, MM. SERRÈS and RÉRAT read a paper on the employment of Colza and Rape, sown in vineyards to preserve the Vine from frost. The seeds are sown in October or November, and by May, when the frosts are most to be feared, the plants have

grown to more than a metre in height, giving good protection. When the frost is fairly gone, the Rape or Colza is cut, and the Vines then grow with more vigour.

— Those who cultivate AURICULAS are often found asserting that it is one of the most satisfying plants to grow, because it always centres about itself so much of continuous interest. A fine old florist once remarked, "If I could grow but one flower it would be Auricula," and Auricula cultivators generally would endorse this remark. The plants are delightfully active just now, putting on their autumnal growth, and the delicious mild weather brings out the charming leaf dress in its pleasantest form. The varieties with mealed foliage appear at their best when they have put on their autumn garb, and especially is this true of Taylor's Glory, Smiling Beauty, Catharina, Earl Grosvenor, Lord of Lorne, White Rival, Vulcan, Pizzaro, C. J. Perry, Martius, Mrs. Sturrock, &c., and it is also remarkable how varied in character the mealed leaves are. In a collection of fifty Auriculas there will be found great diversity of leaf form, for the plants appear to be as far removed as possible from anything like monotony or sameness of appearance in the leaf garb, for let the thick dark green leathery leaves of Colonel Taylor, Lancashire Hero, and George Lighthody be compared with the narrow pale coloured pointed leaves of Richard Headly; the long bold-toothed leaves of Colonel Champneys, and the rounded jagged leaves of Dr. Horner; and these contrasts may be pursued with unceasing interest, and to a considerable extent. It may be remarked that Mr. READ's new grey edge, Dr. Horner, appears to be what the Auricula fanciers term a "good doer," a small plant received a short time since is putting on a vigorous growth. So far there appears a prospect of a good and early bloom—a good bloom because the autumn growth is generous, and the plants are forming those stout filbert centres cultivators like to see at this season of the year; and an early bloom because the plants have been making a good growth almost uninterruptedly since the time of potting. But much will depend on the character of the early spring.

— The committee of the NEWCASTLE-ON-TYNE BOTANICAL AND HORTICULTURAL SOCIETY have with commendable alacrity issued the schedule of prizes for their spring show, which is to take place on April 3 and 4 next. Many societies might take a leaf out of the Newcastle book, for it often happens that schedules of prizes are not issued till two months or so before the show takes place—a haphazard state of things for exhibitors. In looking over the Newcastle schedule we cannot but regret that in the leading class for thirty-six Hyacinths, three bulbs in a 7-inch pot, it is set forth the Hyacinths need not necessarily be grown in the pots in which they are exhibited. It would have been much better to have had a class for thirty-six Hyacinths, grown singly in pots, and the handsome prizes in this class would be certain to bring a good competition. As now expressed the terms are unusual, and favourable to making-up, which is a reprehensible practice in relation to horticultural exhibitions. We are glad to see that all special prizes are swept away from the schedule, for last year many of these were of a most objectionable character.

— Some fine NEW PICOTEES, raised by Mr. ROBERT LORD, Todmoden, and highly recommended by Mr. E. S. DODWELL in the *Florist and Pomologist*, are now being distributed by Mr. J. BOOTH, Failsforth. Miss Horner, heavy rose edge; and Fanny, medium purple edge, were much admired when shown at the exhibitions of the National Carnation and Picotee Society. Mr. Dodwell, a fine rose flake Carnation, is also included in the distribution. Mr. DODWELL reports that this variety "exhibits qualities of the highest excellence."

— Mr. G. SUMMERS, lately of Mentmore, is appointed to succeed Mr. HALL as gardener to the Earl of SCARBOROUGH, at Sandbeck Park.

— Mr. THOMAS TODD, late gardener at Roby Hall, near Liverpool, has been appointed as gardener to J. SLOANE STANLEY, Esq., The Paultons, Romsey, Hampshire.

GROWTH OF BEET.

IN the course of the summer of 1875 I had occasion to take a few observations of the root-growths of some of our garden vegetables, and possibly a note of the rate of growth, that is of the upward or downward progress made weekly at selected points marked along the greater portion of one Beetroot, may be of some interest.

The observations were taken by driving a stick (A A

FIG. 113.—DIAGRAM ILLUSTRATING THE GROWTH OF BEET.

in the diagram, reversed in the engraving, fig. 113), with notches cut in it at distances, firmly into the ground, close to the root, inserting a good sized pin horizontally (weekly) into the root opposite each of these notches, the pin newly placed each week thus giving an easy method of measuring the exact rise or fall which its precursor had made in the previous week from its position exactly opposite the notch. The five vertical lines, with the dates marked above, give the days of examination in August and September, and the short horizontal lines on each vertical one give the exact measure of growth between the date noted opposite the lowest part of each notch and the one immedi-

ately above or below, as circumstances of growth during the week may have placed it.

The figures without horizontal lines show approximate measurement, but not perfectly exactly given like those opposite the notches, the difference in measurement in these small spaces being difficult to note from week to week with certainty.

By glancing at the diagram the growth will be seen to have been very regular at the three upper points, the collective measurements showing a rise of the marking-pin of about three quarters of an inch in five weeks, at the topmost point of measurement, rather less at the second, and less still (rather under half an inch) at the next (the third from the top); but in all these places the growth was upwards, while in the two lower markings the growth was variable, the fourth marking from the top showing no vertical movement, except in an upward direction in the third and fifth weeks of observation; and the fifth mark (placed as near the extremity of the root as it could conveniently be fixed) will be seen to have first progressed downwards and subsequently to have been stationary, then again carried upwards, then downwards, and in the fifth week again stationary.

The Beetroot was of moderate size, and in ordinary circumstances, except in having the earth removed from one side during a few minutes once a week for examination, and the measures give a natural sequence, or extension of growth, except from September 1 to 8, when there was an upward growth at the fourth mark, which, combined with that below and the lesser one above, must have been accompanied with a considerable horizontal enlargement to allow of it taking place. This horizontal extension, however, I had no means of measuring, without disturbing the ground round the root to a degree probably interfering with its steady growth. In a few Carrot and Parsnip roots under observation from about the beginning of August to the end of September the downward progress of the top of the root, sometimes accompanied by the marked point immediately below, being stationary, was traceable week by week. It would be interesting, if possible, to find in these roots differing from the Beet in the great spread of the upper part what is the simultaneous amount of vertical and horizontal growth. This, however, I was not able to manage. I should add that in the diagram of the Beet the five groups of measures are put near together for convenience of space, the root itself was of ordinary size. O.

VEGETABLE REMAINS IN THE EGYPTIAN MUSEUM AT BERLIN.

A FEW years ago the late Alexander Braun delivered a lecture before the Anthropological Society of Berlin on the "Remains of Plants in the Egyptian Museum at Berlin." The notes for this lecture having been found amongst the deceased's papers, Doctors Ascher-son and Magnus thought it was due to the memory of their revered preceptor that they should be made public, and they have accordingly published them in the *Zeitschrift für Ethnologie*. We have been favoured with a reprint, from which we have made the following extracts and abstracts. There are numerous interpolations by the Editors, which it is not necessary to distinguish here. The remarkable discoveries of Professor Oswald Heer in connection with the pile dwellings of the Swiss lakes was the inducement to begin the study of the remains of plants from ancient Egyptian sepulchres, &c., and the fact that Heer determined the Flax he found to be *Linum angustifolium*, and not the now universally cultivated *L. usitatissimum*, first led to an examination of the Egyptian remains. *L. angustifolium* is a perennial species, differing from the annual *L. usitatissimum* in its numerous stems from the same root, and in its seeds and seed-vessels being only half the size. [*L. angustifolium* is sometimes annual, and no wild original of *L. usitatissimum* is known.] As Heer was of opinion that the inhabitants of the pile dwellings were of African origin, it would be particularly interesting to know what kind of Flax was cultivated by the ancient Egyptians. The material at hand was, however, very meagre, only three seeds being found, and it was open to doubt whether they had been intentionally or unintentionally introduced in the collections. One of these seeds belongs to *augustifolium*, whilst the other two are those of *L. humile*, Mill. (*L. usitatissimum*, var. *crepitans*, Schübl. and Martens). The capsules of *L. humile* burst open when ripe, whilst those of the form com-

monly cultivated in Central Europe remain closed. Moreover, the Flax seeds found were mixed with those of two cultivated plants, namely, *Lactuca sativa* and *Nigella sativa*; but the occurrence of *Linum humile* is interesting, because this is the only species cultivated in Abyssinia, where the seeds are largely consumed by the poorer classes as food. It is not impossible that this was the form cultivated by the Egyptians.

Professor Unger conceived the idea of dissolving the unburnt bricks of loam and straw largely used in construction, even in some of the pyramids, for the purpose of detecting vegetable remains accidentally or purposely present; and he found a portion of a capsule of a *Linum*, which he determined to be *L. usitatissimum*. It is probable, however, his determination merely excluded *L. angustifolium*, and that he had not taken *L. humile* into consideration; be this as it may, it ought not to be difficult to ascertain in some of the collections of antiquities what species really was cultivated by the Egyptians. That they grew Flax on a large scale is proved by the fact that their mummies are swathed in linen cloth, and Unger calculated that they cultivated it upwards of 5000 years ago. Although nothing positive resulted from the examination of the Flax seeds, some of the other vegetable remains are highly interesting. Amongst the organic remains detected by Unger in unburnt bricks of undoubted antiquity was *Eragrostis abyssinica*, or Tef, a grain cultivated up to the present day in Abyssinia. This discovery favours the assumption that Tef was cultivated by the ancient Egyptians. In the Berlin collection there is some Wheat (*Triticum vulgare*), mixed with which are a few scattered grains of Barley; and Unger found grains of *T. turgidum* (the prevailing kind now in cultivation in Egypt), and Spelt (*T. Spelta*), and perhaps also *T. monococcum*, neither of which are employed at the present time. Unger also ascertained the fact that from the abundance of Wheat and Barley straw in the bricks of the pyramids of Dabshûr, these cereals must have been extensively cultivated. Numerous grains of *Triticum vulgare antiquorum* likewise occur in the bricks, and this same variety was found by Heer in the remains of the lake dwellings. The Barley was recognised by portions of the ear to be that of *Hordeum hexastichum*. The statement respecting the germination of Wheat from ancient Egyptian sarcophagi was long ago shown to have been based on a deception, and needs no further refutation any more than the fable of a bulb taken from the hand of a mummy afterwards growing.

With regard to the Papyrus, *Cyperus Papyrus*, it includes, without doubt, the inconstant forms with upright and deflected branches of the inflorescence. Different parts of this plant were used for a variety of purposes, as paper, for plaiting, and the starchy rhizome as an article of food. It is worthy of note that a plant once so abundant in Egypt is no longer to be found in that country, whereas in Syria and Sicily, whither it was probably carried from Egypt, it is perfectly naturalised. It is indigenous on the river banks of Tropical Africa, probably extending southward to Natal. The tuberous roots of *Cyperus esculentus*, a plant still cultivated in Egypt, &c., are among the remains.

Apparently the Date Palm had about the same range of old as it now has, being very abundant in the tombs. The real home of the Date is doubtful. Whether the small form found on Mount Sinai is really indigenous or only a colonist is uncertain; but it has an edible fruit. The fruit of the Doom Palm (*Hyphæne thebaica*) is less common. This fruit, which is of a large size, has the peculiarity that often two and sometimes three of the original ovules develop into seeds, whereas in the Date, Cocoa-nut, &c., never more than one reaches maturity. This is quite new to us; we have seen large numbers of the fruit of *Hyphæne thebaica*, but never saw one with three or even two of the cells and seeds developed, and Martius says the fruit is usually simple rarely with two or three cells developed. Dr. Ascherson should know, however, as he has travelled in Egypt and the Libyan desert. A third Palm fruit, found in Egyptian tombs, puzzled botanists for a long time. Kunth named it *Areca Passalacque*, after an explorer; and it has in its ruminated albumen some affinity to the genus, but the fibrous layer in the pericarp is wanting. Unger was the first to identify it with the fruit of *Hyphæne Argun*, Mart., a Palm which inhabits some of the valleys of the Nubian desert in the bend of the Nile between Korosko and Abon Hammed. The unripe fruit, which bears the

names of Argun and Dallock, according to the Belgian traveller, Pruyssenaere, is buried by the natives for a time, whereby the albumen obtains an agreeable flavour resembling the Cocoa-nut. It is recorded by early writers that the Olive was cultivated by the Egyptians, but hitherto the fruit has not been found in any of the graves or coffins. In the Berlin Museum there is an object, similar to the old instrument of punishment, consisting of a number of Olive twigs firmly bound together with strips of Palm leaf; and in the Museum at Leyden there are ancient Egyptian funeral wreaths of the same material. Fruits of a species of *Balsamodendron* in the collection were probably not Egyptian produce, but imported from some parts of the coast of the Red Sea, and remind one of the representation of the booty of Queen Misaphri's fleet on the walls of the Temple of El-Dér-el-bachri. The transport of living trees in tubs is defined in a most characteristic manner, and is designated by the inscription—"Growing incense trees, thirty-one specimens." Fruit of the *Ficus Sycomor* are in the Museum, and most of the objects made from wood are from the wood of this tree, which formerly, as now, was one of the most widely dispersed and most venerated of trees in the country. The fruit, doubtfully regarded as a kind of Orange by Kunth, turns out to be this, as we have been able to determine from a section. It is not smooth, like the common Fig, but covered with a soft wool, and it grows in clusters. The common Fig is also represented in the collection, and seeds of the Castor-oil have frequently been found in the tombs. According to Unger there are fruits of *Cordia Myxa* in the Vienna and Florence collections, but the fruit he designated as such in the Berlin Museum is certainly a very different thing. It is cultivated at the present day in Egypt, and is so distinct a fruit as to be easily recognised by the persistent cup-shaped calyx in which it is seated. A fruit formerly referred to *Mimusops Elengi*, Linn., was proved by a more exact comparison to be *M. Kummel*, a native of tropical Africa. And the seeds supposed by Kunth to belong to a species of *Diospyros*, turn out to be those of the same species of *Mimusops*. It is a remarkable coincidence, too, that leaves of this tree exist in the Leyden Museum, which it appears were taken from the wreaths found with several mummies. These wreaths are often embellished with flowers, amongst which have been recognised those of *Acacia nilotica*, *Chrysanthemum coronarium*, a species of *Centauria*, and *Nymphaea cœrulea*. The seeds of a Cucurbitaceous plant left undetermined by Kunth, are certainly those of the Water Melon, *Citrullus vulgaris*. The identification of these seeds is all the more important, because Water Melons have been found growing wild in various parts of Africa, and there can be little doubt that they were first cultivated in Egypt, whence they have spread to other countries. This is most likely the fruit mentioned as a Melon in the complaint of the Children of Israel, Numbers, chap. ii., v. 5. It is well-known what an important part the Water Lilies, the celebrated Lotus flowers, *Nymphaea Lotus* and *N. cœrulea*, played in the religious ceremonies of the ancient Egyptians. [In this country *Nelumbium speciosum* is sometimes named Sacred Lotus, but Sacred Bean is a more suitable appellation, as it is almost beyond doubt that *Nymphaea Lotus* was the Lotus of the ancient Egyptians. *Nelumbium* is regarded with veneration in India and China.] Professor Caspary recognised two well preserved buds of *N. cœrulea* in the British Museum collections. *Nelumbium speciosum* is represented on the early monuments, and was in cultivation, but it has now quite disappeared from the country, and was most likely originally introduced from Asia. The stones of the fruits of *Balanites ægyptiaca*, a shrub with a fleshy stone fruit, now exceedingly rare in Egypt, is not uncommonly met with in collections from the tombs. Grape growing was extensively practised, as remains and numerous monumental pictures testify. The berries examined were of an oblong shape and probably of a dark blue colour.

Another fruit cultivated was the Pomegranate, the variety differing somewhat from any of those of the present day, in having only four to six cells, instead of six to eight. Seeds of *Sapindus emarginatus*, an Indian tree, have been identified. In India these seeds are used as soap both in cleaning the person and the washing of fine linen, and it is probable that the Egyptians imported them for the same

purposes, as it is known that they had commercial relations with India. *Acacia nilotica* was the only tree of any size producing a durable wood suitable for ship-building, and this only in lengths of at the most 9 to 10 feet. Evidence of the partiality of the Egyptians for the Onion tribe is found on every side. The Garlic, Leek, and Onion, judging from their names, were cultivated, but the remains of bulbs in the collection it has been impossible to identify. We may conclude with a reference to the discovery, by Ascherson, of the wood of *Calotropis procera* in a tomb in the Oasis of Dakbel. *N. B. H.*

Home Correspondence.

The Late Potato Show at the Aquarium.—In reply to your correspondents I have to say that if I have said anything to hurt any person's feelings I withdraw it with an expression of regret. At the same time I am quite sure that the principle I advocated in my note is a sound one, and I have a strong impression that my friend, Mr. Shirley Hibberd, agrees with me in this matter. The reference made in his communication to the temporary provision for refreshments at South Kensington has nothing whatever to do with the subject. I can hardly undertake the duties Mr. Hibberd proposes to thrust upon me, besides which I know that the "arrangements for 1878" will be in abler hands, but I will promise this much, that should the Potato show be held in connection with either the Royal Botanic or Royal Horticultural Societies of London I will do what little I can to help it. Your correspondent, "A Committeeman," seems to me a little bazy when he accuses me of "slandering respectable people, and saying that they go to the shows to drink gin." I never said anything of the kind. I said that no doubt the main object of these joint-stock companies in giving a few pounds to the Potato and other societies was to bring people together to consume the viands on sale at the refreshment bars. If "A Committeeman" thinks their object is the promotion of horticulture, all that I can say is that I disagree with him. The highly respectable names that your correspondent quotes have nothing whatever to do with the subject. Many of them are personal friends of mine, and I esteem them very highly. At the same time I don't agree with the course they adopt in reference to their special exhibitions, but they may be right—I am only expressing my opinion. Your correspondent tells us that the Council of the Royal Horticultural Society offered the Potato Committee £10, and the Aquarium Company, £30; and so it seems there was no resisting the "thirty pieces." Now we all know that the executive of the Horticultural Society is surrounded with financial difficulties, and no doubt £10 was all the Council could offer; and if, as your correspondent says, "the improved cultivation of the Potato" be the object in view—and of this I have no doubt—why was not this donation accepted? I think Mr. Dowell must have misunderstood my meaning—I neither "denounced special shows or specialists." Mr. Wilson asks me if I include the Crystal Palace in the "gin and beer" places? My reply is, I do; and Mr. Wilson must know that the holding of horticultural shows at Sydenham, and the other places I have named, has very much weakened the legitimate societies. For many years past discussions have been going on in the newspapers respecting the embarrassed condition of the Royal Horticultural Society. Mr. Wilson, Mr. Hibberd, and many other gentlemen have taken a prominent part in these discussions, and all I feel sure are anxious to see a strong national society, but we must remember that "union is strength." Now we all know that during the last twenty years elements have come into play which have tended very much to weaken the Royal Horticultural Society—I allude to the holding of exhibitions at the Crystal Palace, Alexandra Palace, the Aquarium, and other places; and if I am rightly informed, the shows held at these places have all been financial failures, so that the state of affairs is something in this wise—the joint-stock companies have lost money in attempting to do work which was previously done by the societies alone, and of course the societies are in a languid state in consequence of the unwholesome competition of the places to which I refer. What is it one hears from horticulturists nearly every day? Why, this—"There are too many shows; one half the number would be

much better." I suppose that the main cause of the present depression in trade is owing to over-production, and this too I think is a cause of the depressed state of the Horticultural Society. What, then, it may be asked, is the cure? To which I reply "fewer shows," and these held at legitimate places. I know full well that you cannot prevent the Aquarium Company or any other from holding a floral show on their premises, but I think horticulturists should be consistent, and if they want a strong national society should withhold their support and countenance from places that tend to weaken and undermine the institution about which they profess such anxiety to build up. I think that our "specialists" should not be unreasonable, and if they cannot get all they want, they ought not to rush into the enemy's camp, for I hold that the Alexandra Palace, Crystal Palace, the Aquarium, and other places which might be named, are enemies to the Horticultural and Botanical Societies of London, and I cannot help thinking but that the managers of the Potato Show would have evinced what I may call a better horticultural spirit if they had accepted the £10, which was all the poor Society could offer, rather than hold the exhibition in a place which, to my mind, seems altogether out of character; and I very much fear that unless more unanimity is displayed amongst the horticultural body, it will be a long time before we shall see a strong national horticultural society. *A. B.*

"A. B." and Special Shows and their Promoters.—Unexpectedly, as far as I am concerned, you have given my remarks publicity, in company with those of gentlemen of weight and authority, and I ask you to permit me to put "A. B." to the question. 1st, What should be the action of florists and horticulturists in the present unhappy paralysis of the central body other than that which has been taken by some amongst them in the past season? And, secondly, Can he supply us with even the hope of a prospect of the cessation of that paralysis? I go on to suggest, as a necessary means for the dispassionate discussion of these questions, that it is most desirable "A. B." shall drop the incognito, for I cannot suppose that either "A. B." or the Editors of the *Gardeners' Chronicle* will maintain that harmony of feeling or unity of action can be promoted by a burlesque of facts or by imputation of petty paltry vanities. Speaking for myself (and I am sure I may say the same for a large number of florists, both of the North and of the South), I declare I shall be delighted to hear of, and combine in, any action whereby I may be relegated to the insignificance of the nobodies—the Browns, and Joneses, and Robinsons—in the presence of the great societies. But "A. B." must not expect either florist or horticulturist to be content with the state of affairs, as indicated by the exhibitions of the Royal Horticultural Society in the season now past. Shows without prizes, or prizes wholly indefinite, and exhibits without competition—all reduced to the dead level of a lukewarm universal commendation—may pass in an emergency, but cannot be sustained. At some future time I may ask your permission to speak of the position of the florist in the republic of horticulture. For the present I content myself with saying that whilst the individual may suffer himself, and willingly, to be relegated to the insignificance of his lot, he will tolerate no slight cast upon the objects of his care—"things" to him, and to a wide world around him, "of beauty—joys for ever." And I have perfect faith that, whilst the perception of beauty is left to us, this feeling will remain. *E. S. Dostwell.* [Our correspondent, "A. B.," and we ourselves deprecate most strongly the introduction of any personal element into this discussion, and if any individual feels aggrieved we can only regret that he should think he has cause to feel hurt. *EDS.*]

Calceolaria Kayii.—A short time ago, when paying my friend and neighbour, Mr. Chard, a visit at Clarendon Park Gardens, I was much struck with the grand display of this once favourite but now uncertain summer bedder. The beds were well filled with plants, having scarcely a death amongst them, whilst the beds so planted were perfect masses of that fine yellow peculiar to the *Calceolaria*. Judging from what I have seen the past summer seemed to have suited the requirements of the *Calceolarias Kayii*, *aurea floribunda*, and *amplexicaulis*, but nevertheless I think some time must elapse before our shaken confidence shall be sufficiently restored to give them that place in the flower garden which, when they "behave well," they are justly entitled to. *H. W. Ward.*

Potato *Magnum Bonum*.—This is proving to be a really splendid Potato in a district where fully two-thirds of the usual varieties are lost through disease. Here *Magnum Bonum* is sound, and is really a grand crop where even Paterson's *Victoria* is very middling, and many of our ordinary Potatos, such as Walker's Improved Regent, &c., are little bigger than marbles. This has been a year of disaster

with *Snowflake*. We dug up a quantity of splendid tubers the third week in August, and there was scarcely a trace of disease to be seen, but in three weeks nine-tenths were as black as tobacco. Those undug were fully worse; those in the fields are scarcely so bad. Porter's *Excelsior* is equally bad, and so is Rector of Woodstock. Scotch Blue is gone altogether; Sutton's *Redskin Flourball* is a fair crop, and is only slightly diseased; *Hundredfold Fluke* ditto, but the quality is extremely poor. These remarks may be interesting to those who have heard favourably of *Magnum Bonum*, and who may be not quite sure whether it is suitable for cold late localities or not, as this is written from a late, cold, exposed district of Scotland, where the soil has been waterlogged all summer through the heavy rainfall and the impervious nature of the subsoil. *A. H.*

Menziesia polifolia alba.—The extreme beauty and usefulness of the white Irish Heath (*Menziesia polifolia alba*) must be my excuse for offering a few remarks on its treatment and suitability for conservatory decoration in the late autumn months, when good flowering plants are getting scarce. Having a stock of nice healthy plants, about a foot to 15 inches high and as much through, growing in the home nursery at a height of nearly 700 feet above sea level, I lifted some of them in the first week of August and carefully potted them, without disturbing the balls too much so as not to injure the roots, gave a good watering, and placed them in a cool greenhouse, where they soon commenced to flower most profusely. Finding how useful and attractive they were I lifted some of them on September 20, treating them in exactly the same way, and they are now a perfect mass of bloom. The pure white bell-shaped flowers, on spikes from 5 to 8 inches in length, produce a most charming effect and beautiful contrast with the neat dark green foliage of the plant, and harmonise well with other plants for conservatory or house decoration. To those who require a really good and lovely white-flowering plant at this dull season of the year I would strongly recommend a trial of it, especially in late localities, as it will well repay its accommodation, even although room under glass is a scarce commodity with many at this season. *C. B., P.*

The Best Cucumber.—There is doubtless much good advice in Mr. Rust's assertion regarding the one kind of Cucumber and Melon, and bearing in mind the old saying, "Speak well of the bridge that carries us safely over," I can truthfully say of the Telegraph Cucumber that it has carried large numbers of our "craft" over safe (myself included): there remains no doubt. We have most of us our favourites—Telegraph is mine for all purposes; and to those who are yet undecided as to which they will grow, I shall not hesitate to say, Take to that variety, and if you have the means to use him well he will prove a true friend. I have had it for these ten or eleven years past, during which time I have grown good fruit from it, and in the following ways:—Outdoor in summer, also in a pit, and trained to a trellis in a house. The latter I find the best for all the year round. I have never yet been troubled with the Cucumber disease, which I firmly believe in most cases to arise from the water applied to roots, quantity or quality of soil, and the state of the atmosphere. I have grown other varieties, and seen them growing in different structures, and would not wish to prejudice others against their favourite kinds. I raise my plants from cuttings, preferring those to seedlings, and as to duration of existence, have upon one occasion cut good fruit from one and the same plant in three successive years. I could give you the details if you wish, as some may think the period of existence of a Cucumber plant would not extend so far, but this latter was an experiment to ascertain how long we could keep it going. As for keeping up a succession, I should plant first week in March and first week in September; but if plenty of light and heat, the March planting would carry round, not cropping too heavy, and giving good attention. *T. Batters, Chilworth Manor, Romsey.*

Peculiar Condition of Cucumber, Tomato, and Vine Leaves.—Herewith I beg to enclose foliage of Cucumbers, Tomatos, and Vines that, as you will observe, are affected with some peculiar disease or rust, being, as they are, so crisp and altogether unnatural. We have been more or less troubled with it all the past season, and at first when it showed itself we attributed it to the dull, sunless weather we had in the early part of the summer. This cannot be the cause though, as our winter Cucumbers are now affected, and the weather has been favourable since they were planted. We first noticed it on some Tomatos and Fig leaves in the spring; it then spread to some young Vines from eyes in an adjoining house, completely spoiling them. We thought at first they had got scorched, so did not then probe into the matter, and only came to the conclusion they were not scorched when we had some more similarly affected later in the season that could not possibly have been scorched. It affected our Melons (all in the same

range) more or less, but not sufficiently so to prevent their carrying fair crops of fruit. The Cucumbers from which enclosed foliage was cut grew away capably at first for some few weeks, now all the growing shoots are same as enclosed, and consequently fruitless. If you can throw any light on the cause or cure of the disease I shall be glad. I may mention that sulphur has been tried with no good results, and also that all the plants, &c., sent have been and are growing under similar conditions that have hitherto given us fairly successful results. *H. J. C.* [We can see no trace either of insect or of fungus agency, the effect is that which anything causing a check to the growth would produce. *EDS.*]

Coloured Vine Leaves.—Do you not think the enclosed Vine leaves, with their autumnal tints, might be very serviceable to a number of your readers, if they had the hint, for decorative purposes, such as harvest festivals in churches, &c.? *J. Peal, Effra Road and Roupell Park Nurseries, Brixton, Oct. 30.* [Yes, certainly. *EDS.*]

Arundo Donax.—In the gardens at Apley House, Ryde, are growing twelve large clumps of this majestically-growing grass, and Mr. David Smith, the skilful gardener at Apley, has informed me this week that some of this year's canes have measured 16 feet high, but it has never flowered with Mr. Smith, neither is he aware of its having done so in any other part of the Isle of Wight, and a more likely place for it to do so is perhaps not in England. The *Arundo Donax* as planted at Apley has a very good effect. It is planted in the centre of a portion of the lawn, and surrounded by its compeer, *Pampasgrass*, which are planted equidistantly but not too closely together. Bamboo—another suitable companion for the above grasses—is cultivated at Apley, where it flowered last year, but at the expense of its life I am afraid, for it has shown no sign of life this year; but, however, Mr. Smith is fortunately in possession of some seedlings which he raised from last year's seed. *H. W. Ward.*

Cinchona in Australia.—Since April last *Cinchona Calisaya* has been continually flowering at Berwick (38° S.), near Port Phillip—plants raised by me and given to a local intelligent settler, Mr. Robinson. It has thrice braved mild frosts. We have much warmer regions in East Gippsland. *F. v. Muller.*

Lapagerias.—It may interest some of your readers to know that plants of *Lapageria rosea* and *L. alba* were planted here (out-of-doors) on April 22 of this year against a wall of the old ruins. The aspect is southern and partly shaded. Both plants have done well and flowered, and that of *L. alba* still retains its flowers. Whether they will stand uninjured during the winter months or not remains to be seen. *G. G., The Abbey Gardens, Battle, Sussex.*

Tomato Culture.—Glancing over a recent number of the *Gardeners' Chronicle* I saw some notes on Tomato growing, as practised by the market gardeners at Fulham, in which the writer remarks that this is what is called a great year for Tomatos. In this favourable county, Cornwall, I have not yet been able to gather one, which, of course, is owing to the unpropitious weather we have experienced this season. I also find that *Solanums* and *Acubas* have a very meagre lot of berries on them. I would like to know how others fare in this respect. *T. P.*

Fruit Trees Productive just as the Soil is Suitable.—While on a visit to Dundee in September last I noticed in the kitchen garden of Mr. Spence, Coventry Bank, Perth Road, a fine lot of pyramidal Apple trees planted alongside the walks, which were perfectly laden with fruit, not one, nor a few, but every one literally bowed down, and I was told that a gale which occurred two days before had blown down bushels, which I could well believe. The trees, too, were in splendid health; indeed, I cannot recall having seen finer ones, and the individual fruits were very fine, the great crop notwithstanding. Let it be borne in mind that 1877 was a year when uniform failure in fruit crops was the general complaint. The soil, I noticed, was on the trap formation, at least so far as I could make out on a very cursory examination, and the hills in the immediate neighbourhood are all trap—the Balgay and the Saw are so, at least so I was informed, as I had not the opportunity to find out for myself. Who has not heard of Newburgh Apples and Pears and Plums?—I allude especially to the residents in the counties of Fife, Kinross and Perthshire. The Newburgh orchards are on the remains of trap, the cliffs at the back being of that formation. I have seen these trees heavily laden year after year with individual fruits much finer than were produced in the Vale of Eden (Howe-o'-Fife), when the trees there were growing stronger and bearing biennially. The soil in

Stratheden is sandy and gravelly. The garden produce of Markinch is famed far and wide, and Markinch lies on the southern slope of a trappean hill. The Lothians are famed for their productiveness, and any one who has seen the Castle Rock, the Calton Hill, Arthur's Seat, and the Salisbury Crags, knows that they are trap, and so are the Pentlands, and most of the stone fences are of whinstone, and whinstone is to be seen in almost every railway cutting in Midlothian. I might cite examples *ad infinitum* were it to serve any useful purpose; but these are facts, and I only want to draw attention to them. When one has a choice of soils, for Vine borders say, or any other purpose, texture alone is not an infallible guide to be carrying about in one's mind. I have seen soils chosen for their texture alone when a choice was to be had, and sometimes the best left behind. What a difference there is in clays! We sometimes hear soils spoken of as aluminous because they are clayey. Aluminous clays are about the poorest soils that were ever seen. Our Scotch carse clays have very little alumina in them, and are often the degraded trap rocks of a former age, and such clays are proverbially fruitful. *A. H.*

The Deciduous Cypress.—This tree is, where it flourishes, as "P. P. C." truly remarks at p. 533, an object of much beauty. And for the information of "P. P. C.," and others interested in such trees, I beg to say that there are two—and those the largest I ever saw of that variety—growing in the grounds here. The larger of the two stands about 100 feet high, and at 4 feet from the ground measures 7 feet 6 inches in circumference. The trunk is comparatively straight and clean for about 40 feet, at which point it assumes two leaders, one of which was broken off some years ago with the wind, and from the same cause it is minus some of its branches, otherwise it is a fine tree of its kind. It is growing in a light gravelly but wet soil within 50 yards of the River Avon, and on a level with its banks. The second and smaller tree is, I think, a good specimen of the deciduous Cypress, and is growing almost in the centre of an angle formed by the confluence of the rivers Avon and Chalk, and within 32 yards of the latter and 35 yards of the former. It is about 45 feet high, with branches touching the ground and 36 feet through. The trunk at 4 feet from the ground measures 4 feet 6 inches in circumference. *H. W. Ward, Longford Castle.*

Shade-loving Plants.—I am anxious to cultivate as many good herbaceous plants as possible in a border a good deal shaded by trees. I find that *Dielytra spectabilis* seems to enjoy the shade as well as the old-fashioned and delicately beautiful *Corydalis lutea*, also *Geranium striatum*, which is extremely pretty and interesting, though it makes little show. We have besides Solomon's Seal and *Campanula persicifolia*, and, of course, *Polyanthuses*, *Primroses*, and *Foxgloves*. Will some one kindly tell me of any other good things which will grow in the shade? What other good *Geraniums* are there? Do the new *Aquilegia chrysantha* and *Skinneri* require sunshine? I shall be very much obliged to any one who will mention some good shade-loving plants. *Trowel*. [*Hypericum calycinum* is one of the best shade-loving plants. *Eds.*]

Tuberoses.—I am glad to notice the article on double Tuberoses, p. 530; a little more information, however, might do much to extend the successful culture of this plant in private establishments. The late Mr. Standish maintained that a minimum temperature was indispensable for the dry root, and if the temperature was allowed to fall below a certain point when the plants were in growth they would all go blind. At the Ascot Nurseries this year I saw a batch of Tuberoses without, I believe, a single failure, and Mr. Ashby attributed this to maintaining a uniformly moist temperature till the flower-buds had appeared. No doubt success or failure is very much dependent upon how the bulbs have been harvested, and the race is between French, Italian, and American roots. Mr. Ashby contends for American; one batch of French bulbs failed with him this last summer to give a flower, although the roots to look at were good, and what were cut showed the flower in embryo. With reference to growing Tuberoses out-of-doors I intend to try the experiment next year; the idea was suggested by seeing a quantity of Tuberoses flowering in the open ground in Holland in the latter end of September. The great demand now is for double Tuberoses; to my liking the single is a more graceful flower, and I should like to see our market growers cultivate the single variety; it would be a better substitute than the double for the September flower. I believe it is not generally known that there is a variety with beautifully variegated foliage. *P. Barr.*

White Blackberries.—Referring to the "white Blackberries," mentioned on pp. 439 and 468, it may be of interest to your readers to note that Ray mentions such a variety of his *Synopsis*, ed. ii. (1696), as

"*Rubus vulgaris major fructu albo*—the common greater Bramble bush, with white berries. *Hujus non fructus tantum colore albo à vulgaris fructu differt, seu et cortex et folia hilarè viridia sunt, cum illius pleumque fasca seu obscurè rubentia abservetur. Found accidentally in a hedge not far from Oxford. D. Bobart." Ray, *Syn.* ii., 309. It is quite evident from the description that it belonged to the "fruticosus" group of Rubi, rather than to the "cæsius" section. A very highly developed bloom on the latter sometimes gives the appearance of a white fruit, but I suppose that in Ray's plant, as well as those of Mr. Bowman and Rev. H. N. Ellacombe, a true albino variety was meant, as unmistakable as in the case of the white Raspberry. *B. Daydon Jackson, 30, Stockwell Road, S.W.**

Potato Disease.—It is a well known fact that after all means that science could devise have been tried to stamp out the disease all have failed up to the present, though in my short experience in the cultivation of Potatoes I have found that the deadly effects may to a certain extent be lessened by change of seed and better tillage. Many useful works are brought out with instruction as to deep digging and manipulating the soil for the growth of the Potato, which is well understood by practical men as essential, and where time permits is no doubt followed up. One of the main points I believe is the manure, which as used in many cases is not suitable, being committed to the soil direct from the stable or pigstye, and that too very often at planting time, in lumps at random, dug in, which in its half-rotted state is ready to catch up and foster fungus or poison the land. Again, I have seen, even in large gardens, a practice which consists of leaving on the land whatever tubers are diseased at lifting time, there to lie and rot down. I have had ample experience that this practice is bad, not only as regards the tubers but also the haulms. In one case this was done on ground which came in for Potatoes the following year. The crop was struck with the blight several days before even a speck could be seen on the other portion of the Potato tops, and at lifting time self evidence was given as to the tubers being very much diseased on the former, while the latter were not even touched, though the whole was treated with a liberal dressing of lime, which I always find beneficial to Potatoes whether mixed with the manure or applied direct to the land. A writer, in his remarks a short time since in the *Gardeners' Chronicle*, said most likely each cultivator, more particularly of prize tubers, had his own pet system; that I will admit. As for myself I cannot claim, nor do I intend to claim, anything original in my treatment of the Potato, but while I can grow crops free from the disease my neighbours lose half theirs. I am therefore quite satisfied as to the result of what I would term a sweet system of culture and manuring of the land. I would advise that no rank manure be in any case used, more particularly at planting time; it is much better when well mixed and worked over in the heap twice or three times during the winter with lime, loam, or sand. Some rich soils, having had a liberal manuring the previous year, would be better without being again manured. In that case I would say add any mixture in opposition to the soil, whether it be lime, sand, clay, loam, peat, marl, or burnt earth; even a little of the bottom spit if the spade is thrust down in digging and brought up will materially change the soil sometimes. Potatoes, I am convinced, want more change. I have seen good samples grown in stuff which has been thrown out of ditch bottoms during the winter and cropped the following year. I will not say that all sorts of Potatoes can be grown alike; it is as well to study which are the best to resist the disease. *R. C. E.*

Vines and Sewage.—I see a notice in the *Gardeners' Chronicle* for October 27, p. 528, of an extraordinary crop of Grapes in a vinery at Woodside, Ipswich, the success of which is attributed to the use of house sewage. It would be interesting to know if the water from the laundry is conducted into the tank mentioned, as the percentage of potash and soda would be by this means materially increased, and would, doubtless, have something to do with the vigour of the Vines in question. *A. H.*

The Parsnip Chervil.—In the issue of the *Gardeners' Chronicle*, October 27, you speak of Parsnip Chervil. The seed of this I have sown year after year for a long time, and never yet succeeded in raising a plant. The foreman at my sample grounds has even been offered a bonus if he could get plants up of Parsnip Chervil, but he has not yet earned either the commendation or the coin. I have often wondered if others in England had been more fortunate. I have consulted our French friends, and they have recommended autumn sowing; still the results have been unsatisfactory. I see in the article referred to that the seed should be kept in sand, to preserve its vitality. I should be glad to know if the seed requires to be placed in the sand immediately after harvesting; if

so, this is an insuperable difficulty in distributing seed. How long does the seed retain its vitality? I have sown it in December in pots, and have failed to get it up. Information on this subject is important to an extension of its culture. Roots of Parsnip Chervil have been exhibited at the Horticultural Gardens, but I have understood the roots have always been imported. It is said to be an excellent vegetable, and it is to be regretted that plants cannot be readily raised. Some of your contributors may, perhaps, have been more successful than I have been. I hope, therefore, to see in your pages the names of some of our leading gardeners stating how they succeed, and what they think of the vegetable, and if they kept the seed in sand, was the sand moist, and how moist? *P. Barr.*

Is it Unusual for Smilax aspera to Flower?—Perfectly hardy out-of-doors, we only have it in the greenhouse (for seven years) in hopes of its seeding as it does in the South of Europe; but until this autumn it has never flowered, and I fear there is no chance of berries at this late season. To encourage the creepers that grow up the back wall and rafters, and the border being very narrow and full of roots, our under-gardener bethought him of laying on a top-dressing of good rotten manure. The result I believe of this plan is the flowering of *Smilax aspera*, many more flowers on the Tea Roses, and vigorous growths on *Stauntonia latifolia*. *T. F. Hope, Wardie Lodge, October 22.*

Fossil Lichens.—The extremely interesting paper published in the *Gardeners' Chronicle* of the 20th inst. on the fossil fungus (*Peronosporites*) leads me to suggest to those who are engaged in the microscopic study of vegetable fossils to give a portion of their attention to the subject of fossil lichens. That lichens are to be found in the fossil state, and will be found when carefully looked for, I do not doubt. I have been looking out for twenty years for published notices of their occurrence; but among my voluminous lichenological notes, accumulated during that period, I find very few references to fossil lichens. There is one, for instance, to the effect that they are mentioned by Brongniart as occurring in the carboniferous flora, just as fossil algae and fungi do. They are also mentioned by Professor Heer of Zurich, in a letter of date July, 1868, and in *Krempelhuber's Geschichte der Lichenologie* (vol. i, p. 431), who refers to species of *Ramalinites*, *Venecaritos*, and *Opegraphites*.* Principal Dawson, of Montreal, suggests that the plants of the Eozoic "may have consisted of gigantic mosses and lichens." With the exception of a number of duplicates, collected mostly in New Zealand, I have long since given to public museums the various vegetable fossils I had collected during the last thirty years, nor am I myself likely to have any other opportunity of hunting for fossil lichens. *W. Lauder Lindsay.*

The Scotch Fir, or Pine.—I read with interest in the *Gardeners' Chronicle* for October 20 your extract from an Aberdeen paper relating to the Braemar Woods, and the excellent quality of the timber produced there, which brought to my mind the old stanza—

"A mile of Don is worth two of Dee,
Except for salmon, stone, and tree."

The banks of the Dee from time immemorial have been famed for their Pine woods. The Scotch Pine, no doubt, grew in the valleys and glens of the Highlands before there were any inhabitants, or at least very few, and before whole forests were burned to expel the wolves; many mountains now covered only with Heather have carried a noble crop of the native Pine, and trunks of trees found in the peat bogs show that the major part of the country must at one time have been clothed with timber. Sir T. D. Lauder was quite enchanted with the Pine forests, and gives the most glowing descriptions of their magnitude and grandeur. The seed of the Pine tree, like that of many others, is so formed that by some means it shall distribute itself; the hurricane which sweeps across the country bears with it the seeds which ever and anon find some sheltered place to rest, take root, and grow into a goodly tree. The rook also, by instinct, spends days and weeks in planting the Fir cones. I have seen them so employed myself. Strange though it may appear, a forest thus planted will take care of itself and grow into magnificent timber, whereas a wood planted with trees of an uniform height and distance apart will completely choke and destroy one another. That the Pine tree was growing at a much greater altitude in the Highlands than now is quite evident, and I can only account for this by the large flocks of sheep and herds of red deer which crop the heads off the young saplings as soon as they start into growth. The Dee is a very rapid running river, so that its banks are naturally dry, and I think the subsol from its source to the sea is gravel, hence the excellence of

* A fossil *Ramalina*, and a fossil Lichen *dichotomus* are described as occurring in the brown coal of Saxony, by Engelhardt.

its timber. It is really surprising what a difference this makes, for I have in my possession specimens of timber of this tree grown on dry land, and also from wet, boggy ground, and the difference of the quality is incredible; that from the first is heavy and full of turps, while the latter is light, and comparatively worthless. The root of the Pine tree lives for a longer or shorter period after the trunk is cut, and often gets very full of resin, when it is dug by the cottagers as fuel, and called "fir." The best is split into thin strips: this is held in the hand as a light. The ancient practice was still continued (thirty years ago) of blowing a horn at 8 o'clock P.M. in winter to let those not possessed of a time-piece know that it was supper-time. Sometimes this "fir" was used for another purpose by poachers: a bundle was tied to the end of a pole, and set a-light, the poachers then waded into the water waist-deep, and once the light was fairly over the salmon it remained motionless till the spear was driven into its gills. Then came the tug of war (for they are strong in the water), and if the fish was large the spearman had to take heed to his footing: many a fine fish has been killed in the Dee thus in the good old times. Nearly all the ancient forests of Dee-side have disappeared before the woodman's axe, but I was pleased to see two years ago the landed proprietors are very wisely planting considerable breadths of the native Pine annually. Let me caution planters to make sure that they get the true *Pinus silvestris*, for there is a spurious variety in the market which comes from Germany. The Arboricultural Society of Scotland is doing good service in this and other countries. *J. Rust, Eridge Castle, Tunbridge Wells.*

Cypella Herbertii.—I am glad to find that Mr. Parker succeeds in growing *Cypella Herbertii*. It is perfectly healthy in the south-west counties. I saw a luxuriant bed of it in a Cornish garden the other day. *H. Harpur-Crewe.*

Iron Supports for Plants.—Is the opinion given at p. 533 with respect to the evils that follow from the contact of plants with iron supports borne out by facts? If it is it will come as a surprise to many persons. Who is there associated with gardening who has not been familiar with Roses and climbers of all kinds trained over wirework, especially in the form of arches, and yet ever noticed any evil effects resulting? In how many gardens are not fruit trees trained to wired walls with the best results, and in many gardens also are not iron hurdles and stout wire used as supports for espaliers, and giving entire satisfaction? Stout wire stretched across the quarters also in many gardens afford excellent supports to Raspberry canes. In one good garden I know of a fine lot of young Pear trees that are trained over a broad path on stout curved iron supports, and these are doing as well as can be desired. Again, how common it is the case that the iron railings of balconies are found covered with creepers of tender growth, yet during the season quite as luxuriant as would be the case on wood. Iron has great conducting power we know, so also have slates, tiles, and stone, yet all kinds of hardy climbers will do well on these as well as on wood. Another common experience is to observe the growth of shrubs of all kinds adjoining and forcing itself against and between iron railings, and yet who ever found any of this the worse for the contact? Galvanised iron and wire is simply coated over with a metallic substance, that enables it better to resist climatic influences, especially moisture, and therefore rust; but it is greatly to be doubted whether it in any way affects the character of the metal as a plant support. Hops, perhaps, might have refused to attach themselves to the metal, but Hops are very sensitive, and the cultivated kinds are almost tender, so subject are they to the changes of the weather. Ironwork, and especially iron wirework, is now so much associated with garden work and culture that strong evidence is required before it can be rejected for such uses. *A. D.*

The New French Roses.—After the observations in your paper of the 13th inst., and the remarks which have since been made by several correspondents, it is surprising that so few of your readers seem to take an interest in this matter of new Roses. Does this apparent apathy and indifference arise from the English Rose growers having made up their minds upon the matter, and decided not to speculate in the purchase of the fifty novelties which are now announced for the first time by the Frenchmen? By-the-bye, upon reading through the descriptions, I find that one enterprising man has found out a new mode of recommending his prodigy. After giving the colour, &c., he goes on to say "nothing has been forgotten in this fine plant"; it would seem by this that perfection has been reached at last. I have no doubt this good man will reap the reward of his ingenuity and originality by having a large sale for this matchless beauty. Roses are like other florists' flowers, every year it becomes more difficult to get a good new variety. This is exemplified by Fuchsias,

variegated and zonal Pelargoniums, Verbenas, &c., but the Frenchmen still find an astonishing number of Roses, to which they give glowing eulphonic descriptions, and which invariably finish up with "twenty-five francs." I believe that by far the larger part of the Roses offered are absolutely worthless, but to get at the kernel you have to buy a very bulky husk, and have to pay very dearly for it. It would be far better to have a few really good, and pay three or four times the price per plant, than be bewildered with a large number of worthless varieties. *Illus. Oct.*

Earwigs.—I can readily give "Hints," p. 537, instructions for ridding himself of these pests. The best way I have found for Peach-houses is a very simple but effectual plan—that is, get some meadow hay, and tie it up in small bundles about 6 or 8 inches long, and put about a dozen on each of the trees every night, taking care to take them off every morning, and burn them. Keep it up for a week, and by that time you will be free from the pests. We have caught thousands in one night by this method. *W. Cook, Gr., Woburn House, Bucks.*

Paraffin-oil and Moles.—It often happens that moles put in an appearance where traps cannot well be placed to catch them, and then it is of some value to know how to shift them easily. This season we were pestered with them in a carpet-border shortly after the plants were put out, and the setting of traps would have made a mess of the arrangements. We, in our dilemma, made small holes over the mole tracks and poured in water tainted with paraffin at the rate of a wine-glassful of oil to a common watering-can, and had the satisfaction of causing the moles to leave the spot altogether. The plan is easy, cheap, inexpensive and effective. *A. H.*

Three-days' Shows and Saturday Terminations.—As one having considerable experience in horticultural exhibitions I would simply ask, Is a three-days' show, terminating on a Saturday, necessary? I for one cannot see that it is. If the arrangement is made to catch the so-called "working classes" why make the termination of a show Saturday? On every day of the week most workpeople give over working at 5 P.M., and from 5 P.M. to 9 or 10 P.M. is quite as much time as most ordinary persons would care to spend at any horticultural show in the country. But if Messrs. Coleman, Wildsmith, Pragnell, Goodacre, and others would just say, "We will not show on such conditions," there would be an end to them. We all know how such matters are arranged—generally by persons who know very little of the practical bearings of the case; and a few hints, such as the present discussion has evoked, may tend to some mutual benefit. *J. McC., Alexandria, N.B., October 23.*

Tuberous Begonias.—Very likely more, much more, is now known concerning the habits and requirements of tuberous Begonias than was known to the late Louis Van Houtte. My instructions were intended, not so much for those intelligent amateurs who always know precisely what to do, and how to do it, but for that much larger and more unfortunate class who would be likely, in consequence of information they had received, to place their Begonias in the autumn on a dry greenhouse shelf, and not reach them down again until the following spring. They would then find the pots and soil and the "mummies." Still it may be possible that a few of the minority class may gather useful hints from my note, for I happen to know some very intelligent amateurs, and also some very practical gardeners, whose Begonias somehow or other contrive during the winter to dwindle away. It must be very patent that there is a vast difference between the uniform condition I require for my tubers and the intermittent one, where they are alternately wet and dry, for they cannot become dry enough to require water without having become too dry; and it is I think quite impossible to water dormant plants of the kind without making them for a time too wet unless you steamed them. A better plan would be to bury them in the natural soil in some situation where they would be safe from the winter rains. To illustrate my uniform theory, I may mention that I had last autumn a large bed in a house of small late-sown seedlings, and these only had time to make the tiniest tubers before going to rest. The greater part were not larger than Mustard seed, and so small that it was quite impossible to pick them out, which, if they had been larger, I should most likely have done, and as the room occupied by them was wanted for other plants these were stood upon the bed, and regularly but carefully watered through the winter. I think it is quite safe to say that out of the thousands in the bed not one perished. They all started freely as soon as the sun began to shine in the spring, and those in a corner of the bed, for a special reason wetter than the rest, started first and strongest. Now for the other side. I had also several pans of the same seedling that were not planted out. These were kept on a dry shelf, and got a drink now and then. These did not begin to grow for a month after the others,

and many not for two months, and then came away much less robustly. When examined during the winter the planted-out ones had full glossy brown skins seemingly bursting with jolly life, and those in the pans were literally "on the shelf," and had skins that resembled much that of a Nutmeg. I feel inclined to say a word upon the proper soil for them, as I never have been successful with old horbed, but enough for the present. The seed-raising must also wait a while. *F. Smith.* [The present race of tuberous Begonias is surely yet familiar to cultivators, so that any information from experienced cultivators like our correspondent will be useful. For example, one would scarcely expect them to stand heavy rains when bedded out so well as they do. *Eds.*]

A Venerable Wild Cherry.—In the article under the above heading which appeared in last week's *Gardeners' Chronicle*, giving the dimensions of an aged tree of "Old Conna Hill, Ireland," the writer requests any readers to state if they know of a larger. Since reading that paragraph I have had the measurements of an old one in the park here taken, and, although not quite up to the size of the Irish one, it is not far behind, especially when taking into consideration that the latter was measured at 1 foot above-ground, where the swell of the roots would likely be above the girth of the stem at 2 feet or 3 feet above-ground. Again, the measurement at 5 feet up shows this to be the case, seeing the girth there to be 19 feet, which is 2 feet 4 inches more than at 1 foot above-ground. It is almost invariably the case that the stem of a tree diminishes in size upwards, from where the expansion of the large roots ceases. The following are the dimensions of the tree here, which I am sorry to say has been decaying for a number of years past:—At surface, 18 feet circumference; 3 feet up, 14 feet circumference; 5 feet up, 14 feet circumference; circumference of spread of branches, 189 feet; height, 33 feet. *J. Webster, Gordon Castle, N.B.*

Autumn Strawberries.—The exceptionally fine weather during the month of September has been very favourable to those who grow late Strawberries. I had several dishes during that month, and on October 16 I picked over 1 lb. of large well-ripened fruit, some of which weighed 1 oz. each. The kinds I grow are Premier and Vicomtesse Hélicart de Thury. I sent them to table on the same day that they were gathered, and my employer and his friends pronounced them better in flavour than the same kinds gathered in June and July last. My mode of treatment is as follows:—As soon as the last fruit is gathered from the pots in spring, the plants are gradually hardened off, and not over-watered: in about a fortnight they are fit for planting out. The ground is well prepared by trenching and manuring. After planting, the ground about them is well trodden, unless it is of a binding nature, which is most suitable to their growth. Plants thus treated will produce more fruit the following season than those layered in thumb-pots will do at two years old. Autumn fruiting does not deteriorate them in the least. I would strongly advise those who have not tried this mode of treatment to do so, as I know they will be well satisfied with the result. *J. Weaving, Gr. to J. B. Evans, Esp., Bylets, Pembridge, Herefordshire.*

Florists' Flowers.

NEW FRENCH ROSE LISTS (continued).—M. E. Verdier's announcement of novelties for 1877-78 has come into the writer's possession since his last paper, and consists of nine varieties. The question naturally arises from their inspection, How is it possible for a single raiser, at one issue, to send forth so many kinds entirely distinct from and superior to any already in established cultivation? It is not as if these fresh introductions were the results of novel experiments in hybridising, but they are all hybrid perpetuals, from which nothing original can be expected, except by rare accident from some untraceable operation of Nature, such as is exemplified by Gloire de Dijon and La France. M. E. Verdier is noted for the number of his annual issues, amongst which some few have been of admitted excellence, M. Niel for instance. Still it must be a repugnant task for importers, warned by perennial disappointments, to undertake selections from one grower only, for which no adequate guide exists, or, on the other hand, of expending money upon the whole set, with the certainty that most of them will turn out unprofitable investments. I often wonder, as the new Rose season comes round, that the leading horticultural journals are not inundated with the "groans of the long-suffering Rose nurserymen," victims to the annual inroads of hosts of mediocrities, pretenders, and importers from the Gallic shores, by which their

patience, their pockets, and sometimes repute, are so sorely tried. It is all very well for buyers to say that it must be a paying branch of trade, or it would not be carried on. This is a shallow view of the case. The Rose public is especially *avidus novitatis*, and dealers must meet their demands even at much trouble, and sometimes even loss. This question, however, is much too large for mere incidental discussion and remark, and will have to be taken up in earnest before very long. Already there have been from time to time murmurings and mutterings which, like distant thunder, betoken an approaching storm, which, when it comes, perhaps, may clear the horticultural atmosphere, which, in some respects, is not at present too cloudless and serene.

M. E. Verdier's nine are:—

H.P. Charles Baltet.—Vigorous, large, full, fine bright carmine-red; extra.

H.P. Charles Duval.—Vigorous, large or medium, glowing scarlet-red; very fine.

H.P. Comtesse de Flandres.—Vigorous, large, full, globular, clear satin-rose; very delicate.

H.P. Docteur Krell.—Vigorous, large, full, large circular petals, deep currant-red shaded purple.

H.P. Mdle. Maria Castel.—Vigorous, very large, well shaped, deep cherry-carmine; very fine.

H.P. Mdle. Marie Verdier.—Vigorous, full, fine shape, bright satin-rose; very pretty.

H.P. President Schlater.—Very large, full, fine velvety rimson-red shaded purple, fiery, and violet. Ought not "feu" to be Englished "flame-colour"?

H.P. Princesse Blanche d'Orleans.—Vigorous, large, full, fine form, Ranunculus-like, rose-carmine shaded purple-violet.

H.P. Souvenir d'Anguste Rivière.—Vigorous, very well formed, rich red-crimson, reflexed, purple and scarlet.

M. Granger makes a singular announcement "of the best of all white Tea Roses," Mathilde, which he describes as having been known by the names of Mouseline, Niphotos, &c. Whether this is put forward as something slightly different from, or an improvement upon our old favourite Niphotos (Greek, snow, a most poetical name) does not clearly appear. Certainly it is one of the best of Teas, and unsurpassed for winter and spring forcing. Boxes of it are sent from France to Covent Garden market twice or thrice a week during the above named seasons. A fine specimen, not too far opened, is equal to a white Camellia as a natural flower for a lady's hair.

The new Roses of English origin for the season, which in time it is to be hoped will work a revolution in that department of the Rose trade, may justly claim a notice to themselves. There is one satisfactory feature about them, that they can be seen before they are bought, not only in the shape of cut flowers, but at the nurseries in actual growth, the true test of what is the true character and value of any Rose.

NOTES ON DAHLIAS.—The past year was on the whole favourable to the production of good Dahlias, much more so than the dry summer of 1876. True it is that the plants were a long time in getting a good start into growth, but when they were ahead they were sustained by a continuance of cool growing weather, with plenty of moisture, that brought forth flowers of great size, and on the whole well finished. Snails and slugs were troublesome in some places, but the compensations stored up in Nature were illustrated by the fact that earwigs vexed less, for it is in hot, dry weather their lawless incursions into Flora's domain are most frequently made.

What is the estimate of the new flowers distributed in the spring of 1877? Some rare good ones were put into commerce, but the drought that prevailed during the blooming season in 1876 prevented the new flowers from being shown in such superb form as the new varieties of the past summer were in September last. When we see little of the seedlings the summer before sending out, we are led to think they are not up to the usual mark, but circumstances are often against the new flowers being shown in the best condition just when a Floral Committee meeting or a Dahlia show is being held.

Of the new flowers distributed by Mr. Turner Artiste (Fellowes) proved what it was represented to be—"a novel and most pleasing variety," the carmine edging to the yellow petals giving the flower a charming appearance; it is of fine build, and has proved very constant. Burgundy (Turner) has a fine purple glow about it, which is thrown over the rich dark puce ground; it has appeared on exhibition

stands in fine condition, and it is a first-rate show flower; Black Knight (Fellowes) is remarkable for its rich dark maroon colour, and is probably the darkest Dahlia in cultivation; on the whole it has come very good this season. Canary (Fellowes) is a singularly fine canary-coloured self, and of great size and fine quality; it should be disbudded freely. Chris. Ridley (Turner) bright glowing crimson, is a flower of superb quality; a bloom of it at the Alexandra Palace show was perhaps the finest Dahlia in the spacious hall. When fully expanded the petals are reflexed, and the surface presents a disc of brilliant colouring. It is already a standard show flower. Drake Lewis (Turner) is very bright in colour, a pure rich scarlet; the quality good all round, and it must be written down as very fine. Elsa (Turner), French-white, is in the way of Herbert Turner, and makes a pretty show flower when caught in good condition. Figaro (Turner) is a constant and novel show flower, ground colour yellow, edged and suffused with bright red; fine form and striking appearance. Mrs. Urquhart (Fellowes) is a chaste-looking flower, white ground heavily tipped with purple; a very good variety, and one Mr. Turner intends to grow largely. The Rover (Fellowes) is a lovely buff self of very good quality, and likely to be useful to exhibitors; Vivian Grey (Fellowes) is of a new and pretty shade of colour—a kind of light brown, but it must be disbudded somewhat freely.

Turning now to the fancy flowers, the six varieties distributed by Mr. Turner have, on the whole, borne themselves well in the season's trial. Edith Turner (Fellowes) has a pure pale yellow ground, delicately tipped with pure white, and has proved a charming exhibition flower; Gamester (Turner), pale buff striped with maroon, has also proved a good, useful flower. Mr. Standish (Turner), yellowish amber ground, suffused with carmine and tipped with white, has not done well this season; probably a drier time would suit it better. Mr. Purves (Fellowes) is another of the yellow ground flowers, tipped with white, and is of very good quality. Oracle (Fellowes) is a full-sized and constant fancy flower, the ground colour bright gold, with dashes and stripes of brilliant crimson. Peacock (Turner) has proved a very fine fancy flower, the dark purple-maroon ground colour being in marked contrast to the distinct white tip; it is also a most effective variety for planting in borders, being very prodigal of bloom.

Of the older show flowers, a few of the very best at Slough this season:—The Acme of Perfection (Downie & Laird), primrose-yellow, a fine and constant variety; Cremorne (Eckford), yellow, tipped red, very fine form; Criterion (Edwards), delicate rose, a flower of great size and fine outline, but a little shallow in the centre; Earl Ravensworth, lively fawn, a sport from Vice-President, and having all its excellent qualities; George Goodhall (Keynes), orange-scarlet; Henry Walton (Keynes), yellow ground, heavily edged with vermilion; Herbert Turner (Turner), French-white, with soft tinge of lilac, a fine exhibition flower; James Cocker (Keynes), a purple self, large, and of fine form, a very constant exhibition flower; James Service (Keynes), dark crimson, large, and fine; John Neville Keynes (Keynes), a remarkably fine and very constant yellow self; John Standish (Turner), bright red, large, and very constant, fine for exhibition; King of Primroses (Rawlings), a large and excellent primrose self; Leah (Turner), golden-yellow self, first-rate quality, fine in colour; Ovid (Turner), a rich puce self, very fine and constant; Prince Arthur (Fellowes), beautiful clear yellow, a fine show flower; Royal Purple (Fellowes), a purple self brightened with lilac; Royal Queen (Eckford), pale yellow ground edged with purple, of good size and fine quality; Thomas White (Keynes), a fine maroon self of excellent quality; and Vice-President (Keynes), a rare old flower of first-class properties.

Of fancy varieties the following are thoroughly good exhibition flowers:—Carnation (Keynes), charmingly flaked with dark rosy purple on a white ground; Dick Turpin (Turner), maroon ground, tipped with white; Fanny Sturt (Pope), red tipped with white, very constant; Flora Wyatt (Keynes), orange striped and flaked with red, comes fine in a self form; Flossie Williams (Keynes), handsomely flaked with purplish crimson on a paler ground; Gem (Pope), dark maroon tipped with white; Henry Glasscock (Keynes), buff striped with crimson: can also be shown as a fine crimson self; Laura Haslam (Fellowes), pale yellow tipped with white; a beauti-

ful fancy; Miss Bond (Keynes), deep lilac striped with dark maroon; Mrs. Saunders, yellow tipped with white, very fine indeed; Pauline (Turner), buff, distinctly tipped with white, fine form; Profuse (Goodwin), maroon tipped with white, a striking and very useful flower; Queen Mab (Turner), white edged with scarlet, very attractive; Rev. J. B. M. Camm (Keynes), yellow flaked with red; and Summertide (Turner), chocolate, tipped and striped with white. R. D.

Notices of Books.

Pollen. By M. Pakenham Edgeworth. With 446 figures. Hardwicke & Bogue.

It is impossible to comment on this work without the expression of a regret that its accomplished author should have allowed it to see the light in its present shape. The author is a botanist of great experience, and has justly earned the esteem of his colleagues. In the present work he has presented us with the results of his observations extending over several years, and with them he has intercalated the remarks that have been made by other observers. Unfortunately, he has in both cases apparently allowed his rough notes to pass into print without revision or collation. The consequence is that an unusual number of errors and misprints are to be found in the volume, many of which, moreover, are no mere typographical errors.

Take for instance the description of the pollen-grains of such *Coniferæ* as *Pinus* and *Abies*. When we come to examine the figures we find scarcely more ground for confidence. The system of measurement is all but incomprehensible, and the forms given to different surfaces of the same pollen-grain are sometimes such as to make us wonder whether they can possibly be intended for representations of the same grain. But we have no desire to enter more fully into particulars, as it is specially distasteful to have to comment on the work of so estimable a botanist, who in this instance has failed to do justice to himself. An experienced botanist or microscopist who would know how to check the descriptions and figures given may find this little book serviceable, as it is certainly convenient to have so many illustrations gathered together for reference. But as a guide to botanical students, and still more as a reference book to that very large class of dilettante microscopists, we are sorry to be obliged to say the book is far from trustworthy.

Physiological Tables for the Use of Students. Compiled by E. B. Aveling, D.Sc. Hamilton, Adams & Co.

Useful as a remembrancer to the student who has first used his powers of observation and memory, otherwise mischievous.

Bulbs and Bulb Culture. By D. T. Fish (Bazaar Office).

A useful little treatise for Villa gardeners and amateurs, who may be glad to have so convenient a brochure at the present planting season. As a matter for the consideration of the publishers may we suggest that the type is painfully small although clearly printed?

SAHARUNPORE, N. W. P. OF INDIA : September 10. *Banyan Fig-Tree*.—In connection with some remarks on Banyan Fig-trees published in your issue of July 28, I may mention that in this garden there is a Fig (*Ficus retusa*, L.) which sends down adventitious roots from its branches most freely; some of these develop into stout supporting pillars. It is a very handsome evergreen tree, with widely spreading branches, and affords excellent shade. Being a rapid growing tree, it is admirably suited for avenue and roadside plantation. Its leaves are much smaller than those of the true Banyan (*F. bengalensis*), and are quite smooth and shining. The growth of the aerial roots is much encouraged by inserting their extremities into columns of heaped-up earth kept continually moist. There are other species of Fig in this garden (*F. elastica* and *F. cunia*) which show a decided tendency to the Banyan-like growth, though in a lesser degree. *J. F. Duthie, Government Botanical Garden.*

Reports of Societies.

Fungus Meeting in Paris.—Meetings of fungologists have of late occupied so much space in this journal that the present record of the Paris meeting can only contain a brief outline of the week's proceedings. The second annual session of the Botanical Society, which is specially dedicated to mycology, commenced on Sunday, October 21, and closed on Friday, the 26th. Previously some of the members had made short excursions, in order to collect specimens for the opening exhibition, and when we arrived at Paris on the Saturday evening these specimens were under arrangement in the large room of the Horticultural Society, in the Rue de Grenelle. The method adopted at Paris is a novel one, and for many reasons not the best, to commence the session with an exhibition. All the results of the week's excursions do not meet the public gaze, and it appears to throw considerable labour and responsibility on the officers of the Society to make excursions beforehand and collect specimens for the exhibition. However, it must be supposed that they have good reasons for such a proceeding, inasmuch as we are in the habit of saying—"They manage these things much better in France."

On Sunday morning, October 21, the exhibition was opened to the public from ten o'clock until five, and during the whole time was well filled with visitors, who appeared to take considerable interest in the subject. About 180 feet of tables were filled with specimens of fungi displayed on white plates, after the manner adopted at Hereford this year. The walls were decorated with water-colour drawings, to the number of 350, by MM. Boudier, Dr. Bull (of Hereford), Cornu, Cuisin, Quelet, Richou, and Seynes. The drawings by M. Boudier were highly artistic, and the most exquisitely finished of any we ever remember to have seen. Unfortunately 700 of these excellent illustrations were burnt during the war. Many of the specimens exhibited on the tables were of considerable interest, but on account of the unfavourable season the fresh specimens were few in number. Several specimens of the rare *Battarrea Gaudichaudii* were sent from Florence. A collection of dried Hymenomyces from M. Barla, of Nice, mounted for the herbarium, excited much attention from the excellent manner in which they were prepared. Each species was accompanied by a coloured drawing and sections, and one or two of the mounted specimens were also coloured up in body colour to a resemblance of life. One species only was mounted on each sheet, and this was sometimes represented by twenty specimens in different stages of growth. Several plates contained the dried fungi sold in the markets in different parts of France, strings of *Morchella deliciosa* from near Geneva, absolutely identical not only in the species, but also in the method of drying and stringing them with those we have received from Cashmere. Of course there were strings of the *Chantarelle* and other species dried in fragments which could not be satisfactorily identified. In the evening at 8 o'clock Dr. M. Cornu gave an admirable popular lecture on the study of Fungi in another room.

Monday, October 22.—The exhibition was again open from 10 to 5, after which it was closed, and the specimens and drawings returned to their owners. About twenty gentlemen met at the railway station after *djehner*, and proceeded on an excursion to the Forest of Saint Germain. Soon after leaving the station strangers were shown the house in which M. Thiers died, and after admiring for awhile the beautiful view of the valley of the Seine from the

elevated terrace on which the pavilion is built, the excursionists dispersed into the forest until 4 o'clock. The large long green boxes of the French mycologists are certainly of an imposing appearance, especially when carried to the extent of one enthusiast on the present occasion, who carried a box at his back nearly 3 feet long, and as broad as his body. Some of the party suggested that it might be used as a sleeping apartment, or as a shelter from the rain. We should think it rather stiff work to beat our way through thick underwood with such an encumbrance at our back.

In the evening, at 8 o'clock, a meeting was held at the rooms of the Society, with M. Ducharte in the chair, when a paper describing some new species of fungi was read by M. Boudier; also one of a similar character by Dr. Quelet, one by Dr. M. C. Cooke on some allied species of *Æcidiiaceæ*, and finally a general conversation on the relations between the larger fungi and cold weather. Dr. Quelet thought that cold was not so injurious as generally supposed, as he had noticed some species revive after frost, especially the *Hygrophori*, and he instanced *Hygrophorus hypotherjus* as not appearing until frosty weather. M. Cornu then reported the names of the species encountered during the excursion of the day.

Tuesday, October 23.—Excursionists were stirring early to leave the station of the Northern Railway by 8 o'clock, for a ride of nearly two hours to the Forest of Villers-Cotterets. This is a large crescent-shaped forest, of 32 miles in length, still inhabited in some parts by wild boars. In the town we were shown the house in which Alexandre Dumas the elder was born, and then went on to the Hôtel Dauphin to breakfast. After a hurried scramble to the station, which is in a remote corner of Paris, and a ride of two hours, breakfast was highly appreciated, and indulged in so leisurely that it was noon before the party were on their way to the forest. Conversation during breakfast was animated on all topics save fungi and politics. It was dark when the party returned to the hotel at 6 o'clock to dine. During this meal some large dried *Polypori* from the Vosges were on the table, and the conversation was very mycological. Dr. Quelet declared that *Hydnum gelatinosum* was an excellent fungus to eat raw, with sugar, like jelly, and of this he spoke from experience. Some Truffles collected during the day were pronounced to be *Tuber mesentericum*, sold usually at five or six francs per kilogramme, or about half the price of *Tuber brumale*. Before the dinner party made their way to the railway station Dr. Cornu undertook the operation of slicing up a large specimen of *Polyporus resinousus*, which had been collected during the day, and was carried by one of the party mounted on the tip of his umbrella and borne on his shoulder. It is noteworthy that in these excursions the party keeps very much together, and whenever anything rare or interesting is found a whistle or a "voilà" brings them all together, the specimen is examined by all before it is consigned to the vasculum, and whenever it is divisible it is divided between those most interested in that particular group to which it belongs. The vivacious and energetic Dr. Cornu, always on the spot whenever required, gave such explanations as the less experienced might desire, or Fries' *Epieris* was brought out and consulted under a tree, doubtful points cleared up on the spot, and if new or rare fresh specimens sought after at once. Paris was not reached again until 10 P. M., and hence no evening meeting could be held.

Wednesday, October 24.—The proposed excursion for this day was abandoned, and, instead thereof, at one o'clock a party which had been organised for the purpose was conducted by M. Cornu through the National Museum and Herbarium at the Jardin des Plantes. In the evening at half-past eight, another meeting was held at the rooms of the Society, when some short communications were read. One of these described a species of *Coprinus* which was developed on a surgical bandage. Mr. T. Howse read a paper on the fungi of the neighbourhood of London, which was followed by a general conversation on the fungi of London as compared with those of Paris; on the fungi of the markets in both countries, and on parasitism of Agarics, such as *Nyctalis* and *Agaricus Loveianus*. Dr. Cornu reported the species found at the excursion of the previous day, which would hardly be of sufficient interest to repeat here.

Thursday, October 25.—The excursion was arranged for Montmorency, only a few miles distance, and consequently did not necessitate an arrival at the station before ten o'clock. Unfortunately, this was a thoroughly reasonable day, raining and pouring alternately, and all operations were conducted under umbrellas, including scratching for Truffles, for this was the "scratch day." Notwithstanding all these little inconveniences five species of *Elaphomyces* were found, some of them in considerable number, and this was no small achievement when it is remembered that they are subterranean and give no certain indication of their presence on the surface, but must be scratched for on "all fours." A most extraordinary crop of *Peziza badia* was found in one place where hundreds

of specimens, some of them 3 or 4 inches in diameter, extended in a scattered manner over about half an acre. In another spot the bird's-nest fungus, *Cyathus striatus*, was in extraordinary profusion, in some cases growing in dense masses 6 to 9 inches in diameter, and prevailing over the whole "clearing" of some acres in extent. In the evening, at half-past 8, the results of the day were announced, and Dr. Cornu explained the structure and progress of the new Vine disease, of which specimens were exhibited. A report by M. de Seynes on the Hereford meeting was also read.

Friday, October 26.—The closing excursion to the Forest of Fontainebleau raised some of us from our beds at 5 o'clock, in order to catch the 7 o'clock train at the other extremity of Paris. After a ride of 37 miles breakfast was welcome, but before it could be partaken of an outlying portion of the forest had to be explored, so that the hotel was not reached until 12 o'clock. Justice to the viands being fully rendered, the exploration was again undertaken, chiefly under the coniferous trees, this being the only spot around Paris where Fir trees are grown to a sufficient extent to produce the characteristic fungi. The shades of evening closed around the excursionists before they again reached the hotel for dinner, and at 8 o'clock the train was due to start for Paris. Dinner having been disposed of, compliments became general, and amongst the toasts which were duly honoured were "The Strangers," "The President" (M. de Seynes), whose unavoidable absence was universally regretted; "The Veteran Fries," "The Woolhope Club and Dr. Bull," "The Author of the *Handbook of British Fungi*," "Messrs. Quelet, Boudier, and Cornu," and "The Mycologists of France," the last two being proposed by the English visitors. Thus closed the Session Mycologique of 1877.

Necessarily this is only a brief outline of the work of the week. Amongst the species found which were of most interest to us were those either not yet found in Britain or very rarely, such as an old dilapidated pileus of *Strobilomyces*, found near Paris for the first time by Dr. Quelet; numerous specimens of the very characteristic *Russula Queletii*, first identified in Britain this year during the Woolhope foray; *Lactarius helvus*, not at all uncommon around Paris; *Cortinari* *scutellatus*, *delibutus*, *isabellinus*, and *paleaceus*; *Irpex paradoxus*, *Coprinus lagopus* and *picaceus*, *Phlebia radiata*, *Hydnum argutum*, *fusco-atrum*, and *molle*; *Hygrophorus discoides*, *Grandinia mucida*, a curious *Marasmius* resembling *M. rotula*, with lateral branches bearing abortive pilei, found in some quantity at Montmorency; *Elaphomyces Leveillei*, *muricatus*, *cyanosporus*, *echinatus*, one *asperulus*, and many other of the larger fungi, which will be recorded in the *Bulletin* of the Society. At one of the evening meetings copies of the design for the Woolhope Club *monu* were distributed and explained by M. Cornu, to the great amusement of the Parisians, although sometimes it was very difficult to translate the point of the humour. The long-continued dry and cold weather which preceded the session was quite unusual, and rendered the season one of the most barren and unfavourable in the memory of the oldest mycologist. *M. C. Cooke.*

The Villa Garden.

FORETHOUGHT.—This is a very necessary attitude of mind in all gardeners, and it is a theme on which many a soundly practical garden homily has been written. A Villa gardener whose love for flowers greatly outpaces the space (very often of an extremely limited character) which he has at disposal for growing them, must be constantly looking ahead, though in doing so he will never miss the enjoyment derivable from the present. While he anticipates the future his soul drinks in all the pleasure forethought in the past has provided for the present time. Faith is often sweetly lost in sight, but it is never wholly absorbed by it; some degree of it is always being projected into the future: he plans and provides—

"Man is the toy of Fate,
His present is at best a moment's space.
We all must face
The unknown to-morrow that in silence wait."

HARDY PLANTS IN POTS.—On what centres the floral hopes of the Villa gardener in the future? Summer has indeed come to a close; the boughs of trees are well nigh naked against the horizon, and ere long the soft, smooth, silent snow will cover them; but all things do not rest in winter, some plants have their resting period when others are at the height of their robust activity, and they put on life and vigour when others are sinking to repose.

A little forethought in summer has given us in the open ground blossoms up to the present time. We have been gathering Roses, especially from a bush of

Gloire de Dijon in a sunny position, Marigolds, Cloves, Gladioli, Mignonette, Asters, Anemone japonica, blue Lobelia, Pansies and Violas, and a few others, up to yesterday. To-day's violent winds and sweeping rain will wreck the chances of further flowers out-of-doors. What is there within? We step into our cold greenhouse and find there the last flowers of Pelargoniums and Fuchsias; Colchicums in pots have been very gay, but are fading away; there is Abutilon Boule de Nieve, a capital bushy French Marigold in a pot, laden with blossom, the golden ground of which is quite lustrous against the gloom without. *Crocus speciosus*—we have had a capital succession of this in pots brought in from the open ground as they threw up their purple buds. *Triteleia lilacina*, and various single and double Primroses, are all yielding pleasant flowers. Outside, still standing in a raised ash bed under an east wall, where there is a little shelter from the driving rain, there are fast coming on towards their blooming time more Primroses, potted early in summer to give them a good start, Lord Lyons and Derby Day forcing Pinks, *Primulas nivalis*, *intermedia*, *marginata*, *purpurea*, *denticulata*, and *farinosa*; *Scilla bifolia* and *sibirica*, *Anemone fulgens*, *A. nemorosa flore-pleno*, the double yellow and double black *Auricularis*, *Violets*, and a few other hardy early flowering plants. These, with a few Snowdrops and Crocuses in pots, will carry the floral service on towards the spring.

As a matter of course it is a great advantage to have a house in which to grow these, and such a house can be erected at a small cost, as no heating apparatus is required, and it can also be placed in a position not so suitable for a heated greenhouse. This kind of cold house is rapidly growing in favour among Villa gardeners; it makes them to a great extent independent of the vicissitudes of weather, and they can get into it and enjoy what is pleasant there undeterred by rain, or snow, or frost without. If the last be very severe a paraffin lamp left burning by night will neutralise its effects to a considerable extent.

The Villa gardener who trusts exclusively to bedding plants in summer has but very little to interest him during the winter; but he who would be always surrounded by pleasant flowers and cheerful-looking plants will gather about him some of the things mentioned above or others of a like character. To imagine they require exceptional care or attention is to do them an injustice; they simply require to be repotted once a year or so, stood out-of-doors till they are sufficiently advanced towards the blooming time to require housing. A number of plants that do not bloom till January, February, or March can be kept in the open air all through the winter if they are plunged in cinder-ashes up to the rims of the pots during the time of their exposure.

In an odd corner, where nothing planted out would grow with advantage, we a few years ago made up an ashbed. The foundation, to the depth of 6 inches, was made up of all the broken potsherds from the house, mingled with brick rubbish; then the contents of the ashbed were sifted, the coarser parts being placed on the layer of potsherds, and the fine ashes reserved for the top of the bed. In this manner a bed some 12 feet in length by 3 feet in width and 12 inches in depth was built up. It is a deliciously cool spot in summer, and, on the whole, cosy in winter; and there is very little in the way of drip from trees near it. The bottom being so cool in summer no plunging is required; in winter it is resorted to when frost threatens to keep the sides of the pots free from its action. Such a bed so formed drains off rain quickly, and cinder-ashes are the best plunging material during winter, as they retain moisture least, and worms do not infest them much.

And when the frost is unusually keen a basket of short hay should be kept at hand to scatter over the plants, burying them to the depth of 3 or 4 inches; and that the hay be not swept away by the wind an old piece or two of carpet or a Russian mat may be added, to be removed as soon as the severity of the visitation has ceased.

A cheap cold frame covered with glass lights might be thrown over the beds at a small cost, and then the plants can be protected from heavy rains as well as frost without the employment of the covering just referred to. Such a frame is never without its uses all the year round. It is such a convenience to the Villa gardener that if tempted to invest in such a frame he will find it an advantageous speculation; it will

incite him to add to his collection of plants some choicer specimens which need a little protection such as the frame affords; and whether it be when spring spreads abroad her robe of green, or the summer's flame deepens to the crimson of autumn and the decaying brown of winter, he will be certain to have ready in his hand something that shall heighten his admiration and deepen his reverence for natural loveliness.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, OCT. 31, 1877.]

Oct. 25.—Overcast, dull, and wet throughout. A miserable day.
 — 26.—Overcast and gloomy till 1 P.M. Fine and bright after. Cloudy at night.
 — 27.—Overcast and dull till 5 P.M. Fine and cloudless after. Heavy rain fell between 3 and 4.30 P.M.
 — 28.—A very fine day. Clear and mild. Cloudless at night.
 — 29.—Overcast, dull and wet till 8 P.M. Fine after. Cloudless at night.
 — 30.—Fine and bright till 3 P.M. Overcast, dull, with strong wind and frequent thin rain after. Mild.
 — 31.—A fine day, partially clear. Mild. Cloudless at night.

LONDON: *Barometer*.—During the week ending Saturday, October 27, in the suburbs of London the reading of the barometer at the level of the sea decreased from 30.13 inches at the beginning of the week to 29.38 inches by the afternoon of the 23d, increased to 29.57 inches by noon on the 24th, decreased to 29.23 inches by the afternoon of the 25th, increased to 29.98 inches by the evening of the 26th, decreased to 29.87 inches by the early morning hours of the 27th, and was 29.90 inches at the end of the week. The mean reading for the week at sea level was 29.68 inches, being 0.45 inch below that of the preceding week, and 0.22 inch below the average.

Temperature.—The highest temperatures of the air observed by day varied from 62° on the 22d to 53° on the 25th; the mean value for the week was 56½°. The lowest temperatures of the air varied from 38° on the 24th to 49° on the 22d; the mean from all stations was 44½°. The mean daily range of temperature in the week was 12½°, the greatest range in the day being 18°, on the 24th, and the least 6½°, on the 25th.

The mean daily temperatures of the air and the departures from their respective averages were as follows:—21st, 51½°, + 2°.2; 22d, 55°.6, + 6°.9; 23d, 48°.3, 0°.0; 24th, 46°. — 1°.9; [25th, 49°.6, + 2°.1; 26th, 49°, + 1°.8; 27th, 49°.5, + 2°.6. The mean temperature of the air for the week was 49°.9, being 2° above the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 109½° on the 24th, 94½° on the 22d and 81° on the 27th; on the 25th the reading did not rise above 54°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 32° on the 24th, 36° on the 23d, and 37° on the 21st. The mean value for the seven low readings was 38½°.

Wind.—The direction of the wind was S.W., and its strength brisk. The weather during the week was dull and wet, but much milder. Fog prevailed on the 26th.

Rain fell on six days during the week, the amount measured was 1.34 inch.

ENGLAND: *Temperature*.—The highest temperatures of the air observed by day were 64½° at Cambridge, 62½° at Blackheath, 61½° at Norwich, and 61½° at Brighton; the highest temperature at Liverpool was 57½°, and at Sheffield and Hull 58°; the mean value from all stations was 60°. The lowest temperatures of the air observed by night were 31° at Wolverhampton, 36° at Leicester, 36½° at Cambridge, and 37° at Nottingham; the lowest temperature at Bradford and Sunderland was 42°, and at Liverpool 41½°; the general mean from all stations was 38½°. The range of temperature in the week was the greatest at both Cambridge and Wolverhampton, 27½°, and the least at Liverpool, 16°; the mean range of temperature from all stations was 21½°.

The mean of the seven high day temperatures was the highest at Truro and Portsmouth, both 59°, and at Plymouth 58°, and the lowest at Hull, 52½°; the mean value from all stations was 56°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 38½°, and at Hull 42°; and the highest at Brighton, Portsmouth, and Truro, all 46½°; the mean from all stations was 44°. The mean daily range of temperature in the week was the least at Liverpool, 8½°, and the greatest at Wolverhampton, 15½°; the mean daily range from all stations was 12°. The mean temperature of the air for the week from all stations was 49°, being 2½° higher than the value for the corresponding week in 1876. The highest were 52° at Portsmouth, 51½° at Truro, and 51° at Plymouth, and the lowest were 45½° at Wolverhampton, and 46½° at Hull.

Rain fell on every day in the week at Truro and Liverpool, and on six days at most other stations. The amounts measured varied from 2½ inches at Brighton, and 1½ inch at Bradford and Leeds, to four-tenths of an inch at both Leicester and Norwich. The average fall over the country was 1 inch.

The weather during the week was milder, dull, and showery. Lunar halos were seen at Bradford on the 21st, 22d, and 26th.

SCOTLAND: *Temperature*.—The highest temperatures of the air varied from 62° at Perth to 53½° at Aberdeen; the mean value from all stations was 58½°. The lowest temperatures of the air ranged from 31° at Aberdeen to 39½° at Glasgow; the mean value from all stations was 37½°. The mean range of temperature from all stations was 21½°.

The mean temperature of the air for the week from all stations was 47°, being ½° lower than the value for the corresponding week in 1876. The highest was at Greenock, 49½°, and the lowest at Aberdeen, 45°.

Rain fell heavily at some places, 4½ inches being measured at Greenock, and 2 inches at Perth; at Aberdeen only four-tenths of an inch fell. The average fall over the country was an inch and six-tenths.

DUBLIN.—The highest temperature of the air was 66°, the lowest 37°, the range 29°, the mean 51°, and the fall of rain 0.44 inch.

JAMES GLAISHER.

Variorum.

AN OCTOBER GARDEN.

In my autumn garden I was fain
 To mourn among my scattered Roses:
 Alas for that last Rosebud which uncloses
 To autumn's languid sun and rain,
 When all the world is on the wane!
 Which has not felt the sweet constraint of June,
 Nor heard the nightingale in tune.

Broad-faced Asters by my garden walk,
 You are but coarse compared with Roses:
 More choice, more dear that Rosebud which uncloses
 Faint-scented, pinched, upon its stalk,
 That least and last which cold winds balk;
 A Rose it is though least and last of all,
 A Rose to me though at the fall.

Christina G. Rossetti, in the "Athenaeum."

FARMING IN WORMS.—Men who are great at catching fish are generally bad hands at that necessary preliminary, fishing for worms; and they will doubtless be very glad to hear of an entirely new industry, that of collecting, breeding, and rearing worms. A worm farm has been carried on in Nottingham with great success, and this is the way it is worked:—Every favourable night—that is, when the ground is wet—several men are sent out into the pastures and meadows of the neighbourhood, and in a single night between 3000 and 6000 worms of various kinds, such as the cocksbur, the lob or dew-worm, and ring-tailed brandling, are caught. The worms are sly animals, we are told, and the men have to be very cautious, for on hearing the slightest footstep they are apt to pop back into their holes. The worms are brought home and placed in properly selected field Moss. A newly caught worm is very tender and delicate, and easily breaks up when attached to a hook, but when

the farmer has properly educated him he is as tough as a piece of india-rubber. Worms cannot be kept longer than a week, as a rule, so before that time the farmer packs them up in light canvas bags and sends them to market, where they are sold by the thousand or the quart. *Cassell's "Family Magazine" for November.*

Obituary.

MR. ROBERT HEWARD, F.L.S., died on October 24, at the advanced age of eighty-five. Though not of late years very closely associated with horticulturists, he was always passionately fond of gardening and botany, and was on terms of intimate friendship with many persons holding prominent positions in the scientific world. In early life, when the Royal Horticultural Society, then the Horticultural Society of London, had its first garden at Kensington, Mr. Heward filled the office of garden clerk, and he continued to do so until after the Society's removal to Chiswick. We have often heard him tell of his having in that capacity assisted M. Sabine in arranging and planting the collection of Crocuses for which the Society was at that time famous, and which form the subjects of several coloured plates issued in its *Transactions*. He also assisted Mr. Liodley in numbering and removing the set of Roses which formed the basis of his *Rosarium Monographia*.

Later on he accepted an appointment to manage a Coffee plantation in Jamaica, in which island he resided for five years, making a considerable collection of dried plants, and especially of Ferns, which were his favourite objects of study, as well as collecting other subjects of natural history at that time little known, some of which found their way to the collection at the British Museum. After his return to England he wrote a valuable and interesting paper on the Jamaica Ferns, which was published in the *Magazine of Natural History* for 1838, and of which separate copies were circulated amongst his friends.

Mr. Heward was on terms of close friendship with the leading Kew employes under the old régime, and to him in a great degree the public is indebted for the reforms which have within the last quarter of a century been so ably worked out in the administration of that establishment, since it was a letter of Mr. Heward's, published in the *Times* that, we believe, led up to the enquiry into the management of these gardens, which resulted in the reforms above alluded to. With the two Cunninghams, Richard and Allan, Mr. Heward was very intimate, especially with the latter, from whom he acquired, by will, the collections of Australian plants collected by him and his brother in New Holland. The distribution of the duplicate specimens of this collection brought Mr. Heward into immediate correspondence with many of the leading foreign botanists of the day, and introduced him to the friendship of such English botanists as Brown, Hooker, Lindley, Webb, Ward, Bennett, Wight, and others of a generation which he has survived. The typical, i.e., Cunningham's own, set of these Australian plants, was a few years since presented by Mr. Heward to the Kew herbarium. Mr. Heward also prepared from the letters and journals of Allan Cunningham, a biographical sketch of his life and labours as botanist to the Australian colonies, which was published in Hooker's *Journal of Botany*. His collection of dried Ferns, which was considerably enriched through the correspondence with foreign botanists above referred to, is now in possession of the writer of these notes, who in late years has shared his friendship, and with other survivors now mourns his loss.

After his return from the West Indies and his re-establishment in London Mr. Heward was for many years intimately connected with the London Press. He was sub-editor of the *Westminster Review* under Colonel Thomson and Sir John Bowring; and as long as strength permitted was Mr. Hansard's principal assistant in preparing for press the far-famed *Parliamentary Debates*. During this time, and till within a few years since, he carried on business as a newspaper agent in Kensington, where he was born and brought up, and where he resided for the greater portion of his life. For a considerable period he held an appointment in the Colonial Office, from which about twelve months since, on account of failing strength, he retired with a pension, and has since resided with relatives in the pleasant town of Wokingham, in Berkshire.

Mr. Heward, who was a great lover of Ferns, made these elegant plants the objects of his special study ;

and one genus, closely related to the Adiantums—consisting, in fact, of net-veined Adiantums—has been named *Hewardia* in his honour, by his old and attached friend, John Smith, formerly Curator of the Kew Gardens.

For some months past his strength, both of body and mind, has been gradually dwindling away, and at length he has passed calmly and peaceably to his long rest, having nearly completed his eighty-sixth year. He was a sincere and true friend, of a most placid temper, full of anecdote of the incidents of early life, a great reader, and with a mind well stored with information on various topics, irrespective of his scientific knowledge, which was comprehensive. He died on October 24, and was buried on Monday last, in Brompton Cemetery, beside his wife, who had by about ten years preceded him on this last journey, and amid the sorrowing regrets of many warmly attached friends. *M.*

— The death of Mr. JOSEPH DURHAM, the eminent sculptor, is also announced. His most important work is the statue of the late Prince Consort in the gardens of the Royal Horticultural Society at South Kensington. We also regret to have to mention the death of Mr. SWINHOE, late Her Majesty's Consul at Ningpo, a gentleman well known in zoological circles, and an occasional contributor to these columns.

— We also hear of the death, on October 28, of Mr. W. J. NUTTING, of Barbican, aged 71.

Enquiries.

He that questioneth much shall learn much.—BACON.
215. PINES SHRIVELLING.—Will some of your correspondents kindly tell me the reason why Pines shrivel in the stem before they are quite ripe? We have two or three fruits of Smooth Cayenne shrivelling in this way, while others are as plump and sound as in a young state. The Pines in question have had a night temperature of 75° to 80°, rising as high as 95° with sun, and a bottom-heat of 90°. *F. P.*

BOX EMBROIDERY: *R. P.* We do not know where you can obtain coloured sheets of designs.
CHRYSANTHEMUMS: *A. B.* The plants may be grown up to a certain stage out-of-doors, but they require the assistance of glass to properly develop the flowers.
GRAPE WITHIN GRAPE.—An instance of prolification. We have met with several cases. In place of a seed a young fruit is formed. We never saw one early enough to trace the course of growth.
GRAPES: *J. Peal.* The Grape has a decided Strawberry flavour. We do not quite understand if you regard it as a novelty. There is a Strawberry Grape in cultivation, and if you will send a leaf and bunch we may be able to say if it differs in any material point.
INSECTS: *Conner & Reid.* The larvae are those of an Otiorhynchus (weevil) or some other small beetle. The eggs of which have been deposited in the soil. There is no remedy, but searching out and destroying them so as to prevent the intrusion of another generation. Saxifrages, Blechnums, and other close tufted-growing plants, are often injured in a similar way by these troublesome creatures.

MEALY-BUG: *G. G.* Methylated spirits diluted with water will answer your purpose, but you must ascertain by experiments as to how much it requires to be diluted, so that it will not prove injurious to the plants.
MENTHA PULEGIUM GIBRALTARICA: *K. E.* We do not know whether this plant seeds sufficiently to make it worth while saving. We have not seen any raised from seeds, the usual and a very quick method of propagation being by division.
NAMES OF FRUITS: *North Riding.* Apple: Frumpling-ton.—*R. G.* 1, May be Cellini, but not certain; 4, King of the Pippins; 5, Striped Beaufin; 6, Old Nonpareil.—*J. M.* We still think the Pear sent is *Beurré Clairgeau*. The difference may be attributable to the stocks on which they are grafted or some similar cause.—*Triomphe de Jodoigne* is very different.—*H. P.* We do not know the Pear you send.
NAMES OF PLANTS: *H. C.* *Saponaria officinalis florenlo.*—*G. G.* sends us seventeen sorts of plants to name. Surely he cannot be aware of the time and trouble this involves. We are very pleased to help gardeners and others who have no means of ascertaining names of plants for themselves, but we must beg them to conform to the rule, and not send more than six at a time. *G. G.* is thoughtful enough to send good specimens. Most that we receive are wretched scraps, quite unrecognisable by the time they reach us. 1, we do not recognise; 2, Pomegranate; 3, *Escalonia rubra*; 4, *Jasminum nudicaule*; 5, *Spiraea cal-*

losa; 6, *Chimonanthus fragrans*; 7, *Kerria japonica*; 8, *Physalis viridissima*; 9, bad specimen—*Spiraea Lindleyana*, if the leaves are pinnate, if not, then probably *S. aræfolia*; 10, *Alonsoa incisifolia*; 11, *Meliathus major*; 12, *Colletia cruciata*; 13, *Berberis Bealei*; 14, *Eunonymus radicans variegatus*; 15, *Saxifrage*; 16, *Dactylis glomerata variegata*; 17, *Elegans japonica*.—*Viator.* *Physalis Alkekengi*.—*J. W.* We cannot pretend to name such scraps—send better specimens.—*L. B. 1.* *Lastrea Filix-mas*; 2, *Lastrea dilatata*, probably; 3, *Polypodium vulgare*; 4, *Lomaria Spicata*; 5, *Asplenium Ruta-muraria*; 6, *Asplenium Trichomanes*.—*M. S.* One of the varieties bred between *B. boliviensis* and *Pearcei*; they are now far too numerous to be recognised by a flower and leaf merely. This may possibly be an unnamed seedling.—*G. S. 1.* *Lastrea decomposita*; 2, *Asplenium bulbiferum var.*; 3, *Athyrium Filix-femina plumosum*; 4, *Adiantum*, specimen insufficient.

PEACHES: *D. W. F.* The following may suit you:—*Peaches:* Early Beatrice, Hale's Early, Grosse Mignonne. *Nectarines:* Elruge, Lord Napier.
PEARS ON MIDSUMMER SHOOTS: *J. D. & Co.* Many thanks. Such cases are not uncommon, but the true fruit—that is, the core—is not formed; the edible portion of a Pear is merely, as in this case, a swelling of a branch.
PRIMULA: *S. Brooks.* Fine, well-fimbriated, and nicely varied in colour—rosy, carmine, blush, and white. It is, as we said before, a very fine strain.
SEEDLING PEAR: *W. Milten.* The fruits sent were large and handsome in appearance, but on cutting them were found much decayed at the core, and with little or no flavour.
STEPHANOTIS: *G. F.* Thanks for the fruit sent, which is a rarity, though we have heard of specimens being perfected at some few other places this season. If the plant gets a tolerably dry rest the ripening of the other fruit is not likely to affect it in any material degree. The fruit, however, is not edible, and can scarcely be of any use for increasing the plant, which strikes freely enough from cuttings.
VINE MILDEW AND SULPHUR: *J. Merrick.* Your practice is nothing new. Every gardener worthy of the name would have done the same thing.
VINES: *H. G.* The following would be a good selection:—White: 1 Buckland Sweetwater, 1 Muscat of Alexandria, 1 Foster's Seedling. Black: 2 Frankenthal, or Black Hamburg, 1 Madresfield Court, 2 Lady Downe's Seedling, or Alicante. The others you name are uncertain.
WINTER HEATH: *Trouel.* If by Winter Heath you mean Erica carnea, the best mode of propagation is to plant it deeply in the soil, when the stems will root, and the old plant can be broken up into patches. It likes a sandy peat and an open situation.

CATALOGUES RECEIVED.—Messrs. Low, Sonner & Co. (Octagon, Dunedin, Otago, New Zealand), General Catalogue of Garden, Agricultural, and Flower Seeds.—Messrs. Froebel & Co. (Neumunster, Zurich), General Catalogue of Plants, &c.—Messrs. Eug. Verdier & Sons (37, Rue Clisson, Gare d'Ivry, Paris), List of New Roses.—Messrs. Howcroft & Watkins (14, Tavistock Row, London, W.C.), Descriptive Catalogue of Flowering Bulbs, &c.—Messrs. Hogg & Robertson (22, Mary Street, Dublin), Catalogue of Forest and Ornamental Trees and Shrubs, Rhododendrons, Conifers, &c.—Martin Grashoff (Quedlingburg, Germany), Special List of Vegetable and Garden Seeds.—Messrs. Bull & Co. (4, Mercer's Row, Northampton), Catalogue of Shrubs, Climbing Plants, &c.

COMMUNICATIONS RECEIVED.—*R. G.*—*A. Z.*—*J. S.*—*J. D.*—*Perrystone*—*J. T. P.*—*C. C.*—*Van V.*—*A. H. P.*—*F. C.*—*W. T.*—*G. T.* (many thanks)—*H. R. I.*—*Cumbrian*—*F. D.*—*M. D.* (many thanks)—*A. P.*—*E. J.*—*R. P.*—*H. P.* and Scotland (next week)—*A. Planter* (you are quite right. It was an error. We will give such a list as you suggest shortly).—*Greenhouse* (we have no information on the subject).—*A. Cockney* (gardener (yes, if you work it up amongst garden refuse)).—*W. G.*—*T. T.*—*A. H. C.*—*W. D. P.*—*E. L.*—*A. H.*—*W. M.*

Markets.

COVENT GARDEN, November 1.

There is scarcely any alteration to quote. Trade is still quiet, with a good supply of home-grown Apples and foreign Pears. Kent Cobs are heavy. *James Webber, Wholesale Apple Market.*

CORN.
Trade at Mark Lane on Monday was dull, the unsettled state of the weather operating as a check to business. English Wheat was about 1s. lower, while a like reduction was apparent in American Wheat; fine dry samples, however, were generally well held. Barley was firm, with an upward tendency. Malt was quiet, and much the same in price. Oats were about 6d. per quarter dearer than on Monday week, while as regards Maize, flat sorts were worth 6d., and round from 1s. to 2s. per quarter more money than the week previously. Beans and Peas were not very strong in tone. Flour was heavy at a reduction of 1s. for sacks.—On Thursday trade was very quiet, and quotations were nominally the same as on Monday, and where there was any pressure to sell lower prices, of course, prevailed. The arrivals of foreign Wheat and Barley were pretty liberal; but as regards Oats, Maize, and other classes of grain supplies were not very good.—Averages prices of corn for the week ending October 27:—Wheat, 53s. 7d.; Barley, 42s. 4d.; Oats, 23s. 8d. For the corresponding period last year:—Wheat, 47s. 1d.; Barley, 38s. 9d.; Oats, 25s. 2d.

CATTLE.
In the Metropolitan Market on Monday trade was very heavy, and prices were not quite so good as on the previous Monday. The weather was very unfavourable, and the dead markets were over-supplied. The demand for sheep was smaller than on Monday se'night, and prices on the average lower. Calves were in demand at fully late rates. Quotations:—Beasts, 4s. 4d. to 5s., and 5s. 4d. to 5s. 10d.; calves, 4s. 6d. to 6s.; sheep, 5s. to 5s. 8d., and 6s. 4d. to 6s. 10d.; pigs, 4s. to 5s.—Thursday's trade continued very quiet. Supplies were extremely short, but amply sufficient for the demand. Both beasts and sheep experienced a limited sale. Fine breeds ruled tolerably firm, but other sorts irregular. Calves were quiet, and without much change.

HAY.
The Whitechapel report for Tuesday states that fodder was only in moderate supply, but the trade was dull, and prices continued flat. Prime old clover, 100s. to 134s.; inferior, 85s. to 95s.; good new clover, 100s. to 130s.; prime meadow hay, 90s. to 107s.; inferior, 75s. to 85s.; and straw, 44s. to 53s. per load.—Thursday's market was moderately supplied with fodder. The trade was better than on Tuesday, and prices were unaltered.—Cumberland Market quotations:—Superior meadow hay, 105s. to 115s.; inferior, 80s. to 95s.; superior Clover, 128s. to 135s.; inferior, 90s. to 110s.; and straw, 52s. to 57s. per load.

POTATOS.
From the Borough and Spitalfields markets we learn that a moderate supply of Potatoes has been on sale, and the demand ruled steady, at about late rates. The arrivals of German reds, Belgian kidneys, and French round Potatoes, have of late been considerable. Kent Regents, 140s. to 160s.; Essex ditto, 120s. to 150s.; Rocks, 100s. to 120s.; Victorias, 140s. to 170s.; flukes, 170s. to 190s.; and kidneys, 120s. to 170s. per ton.—The Potatoes imported into London last week comprised 38,629 bags Hamburg, 5386 Stettin, 1678 bags 400 sacks and 170 tons Dunkirk, 3018 bags Antwerp, 1680 Harlingen, 1602 Ghent, 1318 bags 300 barrels Bremen, 451 bags 837 sacks Boulogne, 200 barrels New York, 197 bags Brussels, 178 Rotterdam, and 72 Dieppe.

COALS.
There was a fair demand for house coals at market on Monday, at previous prices. Wednesday's business showed no alteration. The quotations for the two days were:—West Hartley, 17s. 3d.; Walls End—Original Hartlepool, 21s. 6d.; Hetton, 21s.; Hetton Lycns, 18s. 9d.; Hawthorns, 18s. 9d.; Lambton, 20s. 6d.; South Hetton, 21s.; Vanes, 19s.; South Hartlepool, 19s.; South Kelloe, 19s. 6d.

Indestructible Terra-Cotta Plant Markers.
M AW AND CO.'S PATENT.—Prices,
Printed Patterns, and Specimens sent post-free on application; also Patterns of Ornamental Tile Pavements for Conservatories. Entrance Halls, &c.
M AW AND CO., Benthall Works, Broseley.

SHAW'S TIFFANY, ELASTIC NETTING, CANVAS, &c., for Shading, Protecting, and other Horticultural Purposes. For Samples and Prices apply to **JOHN SHAW AND CO.**, 29, Oxford Street, Manchester.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of 4-in. Pipe.	Price.
High.	Wide.	Long.	Feet.	£ s. d.
20 in.	18 "	18 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	32 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	42 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E. When ordering Boilers please refer to the above advertisement.

WAGSTAFF'S

AGRICULTURAL LOCOMOTIVES,
STEAM PLOUGHING MACHINERY,
ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES,
STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER,

ROCHESTER, KENT: 72, CANNON ST., LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their re-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth pounds of coal per horse-power per hour.

STEVENS'

TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER. Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877. 'GENTLEMEN,—In reply to your enquiry as to our opinion of your Stevens' Trentham Boilers, we do not hesitate to pronounce them to be by far the best Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trentham Boiler, and we have now thirteen of various sizes at work. 'For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trentham Boilers supplied by you, and we have never felt so little anxiety in connection with our hot-houses during the cold winter months as we do now. 'We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion. 'We are, Gentlemen, yours faithfully,

"JAMES VEITCH AND SONS."

For Illustrations, with full particulars, apply to the Sole Makers, F. & J. SILVESTER, HOT-WATER ENGINEERS, &c., &c., Castle Hill Works, Newcastle, Staffordshire. Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

For Sale, a

STEVENS' IMPROVED TRENTHAM WROUGHT IRON HORTICULTURAL BOILER, 6 feet long by 3 feet diameter, fitted with Inlet and two Outlet Pipes, Fire-door and Grate complete. For price and particulars apply to

HILL AND SMITH, Brierley Hill Ironworks, Dudley.

NOTICE TO THE TRADE.

TEBBS' UNIVERSAL FUMIGATOR

Can be obtained Wholesale of FLANAGAN AND SON, Seedsman, 68, Cheapside, London, E.C.; and of CORRY AND SOFER, Shad Thames, London, S.E.

No one cultivating plants under glass should be without one.

AN EXTRAORDINARY BOILER.

During the Great Boiler Contest at Birmingham, in 1872, all Boilers were severely tested to prove their respective merits. One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch pipes, and yet had more than a bushel of fire drawn from its furnace in the morning—equal, in point of fact, to seventeen hours of ordinary firing. What a boon to Gardeners! This was THE CHAMPION, Deards' Patent Close-Coil Boiler, for Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow,

who now have their Boilers at work in every county of England except three. Amateurs will also find THE WONDER, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Prize Silver Medals.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK

VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL RECEIVED MAY 3, 1877.

"The *Kyleys, Alderly Edge, Manchester.*—Messrs. Hill & Smith,—For some 20 years I have used your 'Black Varnish,' and shall be glad if you will forward me another cask, as I consider it the best thing known for the preservation of all outdoor work, either wood or iron, that requires to be painted. —Yours respectfully, ALFRED LOWE, J.P."

Apply to HILL and SMITH, Brierley Hill Ironworks, near Dudley; and 218, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being used by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

MR. MECCHI'S ADDRESS to his OLD FRIENDS and CUSTOMERS and to the PUBLIC:—

"As it has been erroneously supposed by some that I am no longer interested in my London business, I think it desirable to state that I continue to carry it on energetically, and I trust as satisfactorily to the Public, as formerly, assisted by my only son, who will in due time succeed me. It is now fifty years ago since I first commenced business in Loodenhill Street, and what changes have taken place! Then everybody shaved, and my razor and razor-strop trade was immense; now moustache and beard are the order of the day, and the razor and strop trade is comparatively defunct. Then there were no railways, so people stayed at home and used wooden dressing-cases; now everybody travels by rail, and we have dressing-bags to suit the altered conditions. Fifty years ago the poor geese supplied our pens, and many a now rich merchant in the City will remember the quality of Mechi's shilling pen-knives; but steel pens have extinguished the pen-knife trade and the penknapping machines, and the geese are in peace, except at Michaelmas. In fact, steam has altered, and I may safely say, improved everything, and has made us a nation of travellers both by land and sea. I wonder how much time is now occupied in reading the steam-worked press? and how much less time is occupied in sipping port wine, as we used to do fifty years ago, when we could not travel? Steam will make our 4 lb loaves cheaper some day, just as it has converted calico from 2s. 6d. to 6d. or less per yard. Then, again, a letter which used to cost 6s. 6d. to Cork is now carried for 1d. Sir Rowland Hill richly deserves a monument. But to return to business: fifty years ago, when I first commenced on a small scale, I made it an axiom that what I sold should be good and useful, and I do not believe thousands who used the strop and paste, which I personally invented, can testify to this; it fact, it was sometimes complained of that I stamped on my razors 'Exchanged if not [approved.]' I have never, and shall never so long as I live, deviate from that principle, because it is the true means to retain and increase one's connection. I devoted my attention especially to the quality and convenience of arrangements in the dressing bag and dressing case department, and in the tasteful selection of articles suitable for presentation, as well as on the matter of dispatch boxes and writing cases. Although both razors and penknives have 'gone out,' our sportsmen remain, and 'sporting knives' form one of our special departments. I feel firmly convinced that there is no fear of the departure of knives and forks, or dinners, so we make this an important department in quality and price. In conclusion, I ask no favours, but simply desire that my customers should compare the quality and price of my wares with those of other dependable establishments, and form their own conclusions. Most of my worthy assistants and workmen have been nearly forty years in my service, and long ago learned that civility and attention to our customers are as important as good quality in the articles sold. Illustrated catalogues will be forwarded post-free on application."

112, Regent Street, W., opposite Vigo Street.—1877.

Works on Botany, by Dr. Lindley.

DESCRIPTIVE BOTANY; or, THE ART
OF DESCRIBING PLANTS CORRECTLY, in Scientific
Language, for Self Instruction and the Use of Schools. Price 1s.

SCHOOL BOTANY; or, THE RUDDIMENTS
OF BOTANICAL SCIENCE. In One Volume, 8vo, half bound,
with 400 Illustrations, price 5s. 6d.

**THE ELEMENTS OF BOTANY, STRUC-
TURAL AND PHYSIOLOGICAL.** With a Glossary
Technical Terms and numerous Illustrations. 9s. cloth.

This completes the series of Elementary Botanical Works by
Professor LINDLEY, of which *School Botany* and *The Vegetable
Kingdom* form the other parts.

The first two Parts of *The Elements of Botany*, comprising
Structural and Physiological Botany, and a Glossary of Techni-
cal Terms, are published in one 8vo volume, price 9s.

These three Parts form a complete Manual of Botany for
Medical and other Students who have made themselves
acquainted with the Author's *School Botany*.

N.B. The Glossary may be had separately, price 5s.

THE ORCHARDIST.

ALL FRUIT GROWERS SHOULD OBTAIN A COPY BEFORE
ORDERING THEIR TREES.

Apply to J. SCOTT, The Royal Nurseries, Merriott, Somerset,

Whose Collection is the finest in the Kingdom—2000 sorts of PEAR, 1500 sorts of
APPLE, 150 sorts of PLUM, with other kinds in proportion, being grown. The great bulk
of these are described in the "ORCHARDIST," the best work on Fruit Trees in the English
language.

The Advertiser has numbers of Letters from Britain, America, Australia, France, Belgium, &c.,
all eulogising the work as the best the writers have seen.

The Trees are this season in fine health. Price Lists forwarded.

Florist and Pomologist, &c.,

Assisted by several eminent Practical Gardeners.

LONDON: BLACKIE & SON, PATERNOSTER BUILDINGS, E.C.,
AND SOLD BY ALL BOOKSELLERS.

Dr. Lindley's Theory of Horticulture.

In 8vo, with 98 Woodcuts, price 21s. cloth,
THE THEORY AND PRACTICE OF HORTICULTURE; or, an Attempt to Explain the Chief Operations of Gardening upon Physiological Grounds; being the Second Edition of the *Theory of Horticulture*, much enlarged. By JOHN LINDLEY, Ph.D., F.R.S.

"The first edition of this valuable work was issued in 1840, since which time it has had an extensive circulation, and has been translated into the German, Dutch, and even Russian languages. Being more particularly restricted to principles, however, the author at length resolved to render the work more generally interesting and useful by a more frequent reference to practical operations. He has thus greatly extended the matter by supporting the physiological doctrines with an appeal to facts familiar to cultivators, or which ought to be; and the result is a still more interesting and popular compendium of the principles and practice, or the science and art, of horticulture."—*Builder*.

"This is a second edition of the *Theory of Horticulture*, with the addition of a large quantity of practical matter, introduced to show how entirely scientific principles and good cultivation correspond. The volume contains about four times as much matter as the first edition. . . . Although very large additions are made to every chapter, while many passages in the first edition have been wholly struck out, it may be proper to say that the greatest changes are those which relate to vitality, climate, domestication, ventilation, propagation, pruning, resting, and soils and manures; such being the subjects in which practical men are most interested. The whole work has, indeed, assumed such a form as to make it evident that the great object of the author has been, not to produce a work suited to men of science, but one which every well-informed person may understand and apply. As the volume concludes with a very copious index of matter, there is no difficulty in finding where any given subject is treated of."—*Gardeners' Chronicle*.

London: LONGMANS, GREEN, AND CO., Paternoster Row

Dissolution of Partnership.

PARTNER WANTED, for a large Horticultural Establishment in Belgium. Capital required, from £5000 to £7000.—A. B. C., Poste restante, Bruges, Belgium.

Borough of Longton.

THE TOWN COUNCIL are desirous of receiving applications for the Office of REGISTRAR for the New Cemetery. Persons applying must have a thorough knowledge of Gardening, and be able to set out the Graves and keep the necessary Books and Register. The salary will be £75 per annum, with house, coals and gas.

Applications, enclosing testimonials to be made to the Chairman of the Cemetery Committee, endorsed "Application for Registrar," addressed to the Court House, Longton, on or before Tuesday, November 6.—By order, ARDEN HARDWICKE, Borough Surveyor.

WANTED, IMMEDIATELY, a thoroughly competent GARDENER (Single-handed), unmarried, to take Charge of a small Flower and Kitchen Garden, Cows, &c., and fully understanding Glass. Unexceptionable references required.—Address, by letter only, stating age, experience, and wages required, to T., Fairmile Cottage, Cobham, Surrey.

WANTED, as JOURNEYMAN in the Houses, a steady, industrious young Man, about 22; must thoroughly understand the Watering of large Stove and Greenhouse Plants, &c. Wages, 18s. per week, and bothy.—GEORGE SMITH, Gardener, The Street, near Rivington, Chorley, Lancashire.

WANTED, a strong YOUTH, to assist in a Seed Warehouse; must be acquainted with Names of Vegetable and Flower Seeds, spell correctly, good Penman, Write upon and Wrap up Parcels, &c.—S. FINNEY AND CO., Seed Merchants, Newcastle-upon-Tyne.

WANT PLACES.

E. G. HENDERSON AND SON have many excellent GARDENERS with approved testimonials for their ability oow waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners.

JOHN LAING AND CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park and Rutland Park Nurseries, Forest Hill, London, S.E.

W. H. ROGERS, NURSERMAN and LANDSCAPE GARDENER, Southampton, will be happy to wait on Gentlemen in any part of the Kingdom, to advise respecting PLANTING and LAVING-OUT of GROUNDS of every description. Terms on application.

E. P. DIXON can at present recommend several excellent GARDENERS, and will be pleased to answer any enquiries from Ladies and Gentlemen requiring such.—The Yorkshire Seed Establishment, Hull.

GARDENER (HEAD), and GENERAL MANAGER—JOHN TAYLOR, who has been Gardener and General Manager for the Hon. P. T. Wyndham, M.P., at Ise Hall, Cockermouth, Cumberland, for the last five years, is now open to treat for a similar situation; will be disengaged at Christmas. First-class testimonials.—Address as above.

GARDENER (HEAD).—Age 31, single; thoroughly understands Early and Late Forcing; Kitchen and Flower Garden. Five years' good character.—G. D., H. Sprigings, Orchard Street, St. Alban's, Herts.

GARDENER (HEAD).—Age 28, single; thirteen years' practical experience in the general routine of Gardening. Good character.—C. L., Stoodleigh Court, Tiverton.

GARDENER (HEAD).—Married, no family; well experienced in all branches of the profession, Early and Late Forcing. Thirteen years in last situation. Good character.—G. J., G. Cooling, Nurseryman, Broad Street, Bath, Somerset.

GARDENER (HEAD), to any Nobleman or Gentleman requiring the services of a first-class Gardener.—Age 40, married; thoroughly understands the profession in all its branches. First-class references.—E. BUTLER, Moira Cottage, Ranelagh Street, Leamington.

To Nurserymen and Others.

GARDENER (HEAD, WORKING), age 38, single.—£5 would be given by the Advertiser for a comfortable situation as above. Good character.—W. T., 22, Harcourt Street, Marylebone Road, London, N.W.

GARDENER (HEAD, WORKING).—Age 26, married; thoroughly understands Stove and Greenhouse Plants, Vines, Peaches, Melons, Cucumbers, Flower and Kitchen Gardening. Good references.—A. B., Hatching Green, St. Alban's, Herts.

GARDENER (HEAD, WORKING).—Age 47, married, no encumbrance; steady and energetic; well up in all the branches; has a knowledge of Meadow Land and Stock if required.—W. H., Loughton Post-office, Hawkhurst, Sussex.

GARDENER (HEAD, WORKING).—Age 39, single; thoroughly practical in all departments of Gardening. Fourteen years' excellent character for integrity and capability. Please state particulars.—A. P., Rev. J. Savage, Rowland's Castle, Havant, Hants.

GARDENER (HEAD, WORKING).—Age 35, married; thorough practical knowledge of Gardening, including Flower, Fruit, and Kitchen Gardens, Pleasure Grounds, Vines, Pines, Plants, &c. Well recommended.—B. B., 17, Londesborough Road, South Hornsey, N.

GARDENER (HEAD, WORKING).—Age 30; thoroughly experienced in the Cultivation of Orchids, Stove and Greenhouse Plants, Pines, Vines, Peaches, Melons, and Flower and Kitchen Gardening. Good character and reference.—H. T., 2, High Street, Somerton, Chichester.

GARDENER (HEAD, WORKING).—A GENTLEMAN wishes to recommend a Man and Wife—Man as Head Working Gardener: he thoroughly understands the profession (age 30). The Wife has had charge of House during absence of Family, and would do so again if required. Have lived in present situation four years and eight months. One child, 6 years old.—J. SIMMONS, 34, East Street, Red Lion Square, High Holborn, London, W. C.

GARDENER—WM. HINDS, Gardener to Sir Thomas Edwards-Moss, Bart., Otterspool, near Liverpool, can with every confidence recommend a man who is thoroughly experienced in all branches of the profession, and who has acted in a similar capacity in a first-rate establishment.

GARDENER—JOHN COWAN, The Vineyard, Garston, near Liverpool, would be glad to recommend to any Nobleman or Gentleman requiring a first-class Gardener a Man in the prime of life, who thoroughly understands the profession in all its branches, having had many years' experience in some of the best places in England and Scotland.

GARDENER (SECOND), in a Nobleman's or Gentleman's Establishment.—Age 23, single; well up in Forcing Fruits, Flowers, and Vegetables. Two years in last place as Second. First-class character.—B. D., Sutton Park, Guildford, Surrey.

GARDENER (SECOND), or JOURNEYMAN.—Age 23. Good reference.—W. C. H., 3, Denmark Place, South Ashford, Kent.

GARDENER (UNDER), where one or two are kept.—Age 22. Good character.—Address, stating wages, to J. ROFE, Market Place, Cranbrook, Kent.

GARDENER (UNDER), in a good Establishment.—Age 23; six years' experience in all branches. Good character.—H. W., 15, Mount Ash Road, Sydenham Hill, S.E.

GARDENER (UNDER), or IMPROVER.—Age 19; five years' experience. Two years and three months' character from the place now leaving.—Apply, stating wages, &c., to H. J. F., Post-office, Ascot, Staines.

FOREMAN, in a Nobleman's or Gentleman's Garden, age 24.—Archdeacon VESSEY can recommend a steady, experienced Man as above. Good references.—HEAD GARDENER, Castle Hill House, Huntingdon.

FOREMAN, in a Gentleman's Garden.—Age 24; has a good general knowledge of House-work, Flower and Kitchen Gardening, Pruning, &c. Three years' good character.—A. M., Post-office, Wood Green, N.

FOREMAN, indoors preferred; age 26.—The HEAD GARDENER, Burton Constable, Hull, is desirous of procuring a situation in a good Establishment as above for his Foreman.

To Nurserymen.

FOREMAN, or FOREMAN and PROPAGATOR (INDOOR, OUTDOOR, or both).—Long experience in the Cultivation of Roses, Fruit Trees, Conifers, Greenhouse Plants, &c.—Address, stating wages, &c., to HORTUS, 6, Clarina Road, Penge, Surrey.

To Nurserymen.

FOREMAN and PROPAGATOR (INDOOR).—A. ANDREW, Nurseryman, Kilmarnock, N.B., wishes to recommend a thoroughly qualified Man, where Stove and Greenhouse Plants are grown extensively. Has fifteen years' unblemished character.—Particulars, &c., address as above.

To Nurserymen.

FOREMAN and PROPAGATOR, or SALESMAN, in a Nursery or good Market Garden, where choice Fruits and Flowering Plants, &c., are grown for Market.—Age 37, single; well up in Working Roses, &c., under Glass. Twenty years' experience in London Nurseries. Country preferred. Five years' character.—X. Y. Z., Pixham Grove, Dorking, Surrey.

MANAGER, FOREMAN, or FOREMAN and PROPAGATOR.—Practically acquainted with the profession in all its branches, including the Growth of Plants and Flowers for Market.—ALPHA, Simpson's Library, Lower Sydenham, S.E.

JOURNEYMAN, under Glass preferred.—Age 21; accustomed to Vines, Peaches, Pines, Melons, Cucumbers, Plants, &c. Good character.—W. CONNELLY, Lower Bullingham, Herefordshire.

GROOM and GARDENER (or SINGLE-HANDED, or SECOND).—Middle-aged, one child at home; Cows objected to. Wife good Landress. Many years' reference.—HORWOOD, Hagley, Stourbridge.

TO MARKET GARDENERS, &c.—A married Man (age 26) desires a situation as Grower of Market Plants and Cut Blooms of choice varieties. Has had good experience in Building, Pipe Laying, Boiler Setting, and in Growing Grapes and Bedding Plants in great quantities. Good character.—B. B., 26, Wellington Road, Camberwell, Surrey.

IMPROVER, in a good Establishment.—Age 20; has served five years under Glass. Can be highly recommended.—EDWIN MAISEY, Walton Gardens, Warwick.

IMPROVER, in the Houses.—Young; six years' experience. Character undeniable.—S. W., 12, North Street, Eastbourne.

IMPROVER.—A Youth, son of a Nurseryman, seeks employment in a Leading Nursery, or where Fruit is grown extensively; would devote his time and energy to the interests of his employer, and would be willing to make himself useful in any capacity.—B. M., Messrs. Flanagan & Son, 98, Cheapside, London, E.C.

SHOPMAN (HEAD).—Age 29; eleven years' experience in leading Wholesale and Retail Houses; good knowledge of plants. No objection to Travel, London preferred. First-class references.—M. W., Mr. G. Taylor, 15, Ave Maria Lane, Ludgate Hill, E.C.

BOOK-KEEPER, CLERK, or SHOPMAN, in a Nursery or Seed Business.—Age 32. First-class references.—K. W., 32, West Parade, Rhyl, North Wales.

TO THE SEED TRADE.—A young Man (age 20), who has had several years' experience in the Seed Trade, seeks an engagement in a London Wholesale House. Good references.—G. L., *Gardeners' Chronicle* Office, W.C.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

GRATEFUL—COMFORTING.

EP P S S'S (BREAKFAST) C O C O A.

JAMES EPPS & CO., HOMOEOPATHIC CHEMISTS.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants. DINNEFORD AND CO., 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S OINTMENT and PILLS.

—Health's Defences.—None save the strongest can with impunity pass through the sudden transitions from wet to dry, from cold to muggy weather, so prevalent during the late autumn and early winter months. Influenza, bronchitis, cough, sore throat, diphtheria, or quinsy, will attack those most watchful of their health; but they can readily arrest any of these complaints by rubbing Holloway's Ointment twice a day upon the skin adjacent to the affected part, and by assisting its corrective action with appropriate doses of his Pills. This well-known, safe, and easy mode of treatment efficiently protects the invalid both from present and future danger without weakening or even depressing the system in the slightest degree.

PAXTON'S CALENDAR.

Now Ready, a New and thoroughly Revised Edition of the

COTTAGER'S CALENDAR OF GARDEN OPERATIONS.

ORIGINALLY COMPILED BY THE LATE SIR JOSEPH PAXTON, M.P.

OPINIONS OF THE PRESS.

"It has been carefully revised by an experienced gardener, and the lists of vegetables, fruit, and flowers have been corrected by the substitution of the most approved modern kinds, in place of those which were mentioned in the first edition, and many of which have ceased to be worthy of cultivation. It is a thoroughly sound, practical treatise; but it has been so long before the public, and so deservedly appreciated, that any special commendation of it now is unnecessary."—*Midland Counties Herald*.

"This is a handy volume, consisting of seventy pages of letterpress and illustration, containing much and varied information likely to prove useful to all cottagers, &c., who possess a garden. To all such, who require a cheap and reliable book of reference, we heartily recommend it."—*Lloyd's*.

"We are quite glad to see this useful little book once more, and it is like a whiff of perfume from the heather in bloom to read on the wrapper 'two hundred and twenty-first thousand.' We advise all who are interested in the promotion of cottage gardening to sow this little book broadcast."—*Gardeners' Magazine*.

"The information conveyed in this little book is well adapted for all persons having small plots of ground. The necessary operations for each month are clearly laid down, and are of a thoroughly practical nature. The sorts of both fruit and vegetables are well selected, many of them being excellent in quality. To our readers who are interested in the cultivation of their flower and kitchen gardens, we can safely recommend this as being a most concise and useful work."—*Bell's Messenger*.

Odontoglossum pardinum, Reich.

MR. J. C. STEVENS has been instructed by Mr. Sander to sell by AUCTION, for account of Mr. B. Roetzl, on **THURSDAY**, November 15, at half-past 12 o'clock precisely, at his Great Rooms, 38, King Street, Covent Garden, W.C., an importation just to hand, per steamer *Nile*, of this magnificent **NEW GOLDEN ODONTOGLOSSUM**. It is described in the *Gardeners' Chronicle*, March 10, and Dr. Reichenbach received a spike of its beautiful flowers, many golden-yellow and brown-spotted, from Mr. F. Mill, with over forty flowers expanded. Mr. Klaboch, who sends home the plants, says that it grows in a very cold region; the flower-spikes are from 3 to 4 feet long, and from 2 to 3 feet in diameter, closely branched, and covered with from 100 to 200 large flowers, these measure individually $\frac{3}{4}$ inches across; its colour is dazzling, and it remains in flower for a period of from three to four months. He considers it the finest yellow *Odontoglossum* extant. At the same time will be offered **ODONTOGLOSSUM MACULATUM DOWIANUM**, Reich., fully described in *Gardeners' Chronicle*; the magnificent **MAXILLARIA GRANDIFLORA**, **ODONTOGLOSSUM CIRRHOSUM**, **BARKERI**, **LEDOLEANA**, **TRICHOPLIA**, **ORTHILIS**, **ONCIDIUM UNGUICULATUM**, an importation of **ODONTOGLOSSUM KARWINSKI**, large masses of **CATTLEAS**, **ODONTOGLOSSUM MADRENSE**, **LYCASTE SKINNERI**, and other Cool ORCHIDS.

CATALOGUES free on application.

HENRY DERBYSHIRE, Darley Hillside Nursery, near Matlock, Derbyshire.

NOVELTIES FOR 1878.

JAMES VEITCH & SONS

DESIRE TO DIRECT ATTENTION TO THE FOLLOWING NEW AND CHOICE SEEDS:—

NEW PEA, "CRITERION" (Standish).

This exceedingly fine New Main Crop Pea is one of several seedlings raised by the late Mr. John Standish, who for some years devoted much attention to hybridising and improving the quality of this vegetable, and from whose executors J. V. & Sons have purchased the whole stock of his Seedling Peas.

Criterion is supposed to be a cross between Advancer and Ne Plus Ultra, and was considered by the raiser to be one of the finest of his seedlings. In general appearance it partakes much of the character of the Ne Plus Ultra, while, as a second early, coming into use somewhat in advance of Champion of England, it is valuable on account of its fine quality and free cropping properties.

The plant is of a strong robust branching habit, and grows from 5 to 6 feet in height. The pods, which are produced in pairs, are of a deep olive-green shade and exceedingly well filled, generally containing from seven to nine Peas. These are of a fine deep green colour, and remain a long time fit for use. When boiled they are of a fine rich flavour, and, retaining their beautiful deep green shade of colour, have a very attractive appearance on the table.

Mr. DRAPER, *The Gardens, Seaham Hall*, says:—"Your New Pea has proved to be a first-class sort, suitable for general crop. It has six to eight Peas in a pod, of large size, and it is also a good cropper, and the pods are well filled. I exhibited it at the Seaham Horticultural Show, and got First Prize, against seven others."

Mr. JONES, *The Gardens, Bentley Priory*, says:—"I have formed a very decided and favourable opinion of your New Pea, Criterion. With me it grew about 4½ feet high, with a mass of beautiful green pods, averaging eight peas in each, with the look and flavour of Ne Plus Ultra, and being so early I think it just the Pea wanted."

From *The Florist*:—"Messrs. Standish & Co., of Ascot, who have raised a very promising batch of New Peas, have just adopted the name of 'The Criterion' for that which has been set apart as the best of the series. It is in every way an excellent Pea. Being one of the Wrinkled Marrows it has a fine sweet flavour. It is in use a fortnight earlier than Ne Plus Ultra, and is a good bearer, with well filled pods, resembling those of Laxton's Supreme, and having thick fleshy husks. When cooked it is of grass-green colour, and, being of a delicate texture, it will, it is said, keep longer to use than any other Pea, partaking, in this and in other respects, of the character of Ne Plus Ultra, which was one of its parents. We look upon the Criterion as one of the most valuable of the New Peas."

Mr. BREESE, *The Gardens, Petworth Park*, says:—"Criterion was sown under the same conditions and on the same day as British Queen and Ne Plus Ultra. I think it is a finer looking Pea than either of these, a heavier cropper and finer looking pod, and quite a week earlier. It is undoubtedly a good Pea."

Mr. MCINDOE, *The Gardens, Hutton Hall*, says:—"Criterion, when boiled, has a beautiful dark green colour and a most delicious flavour. I think it cannot fail to become a great favourite where high-class deep green Marrow Peas are esteemed."

Mr. GILBERT, *The Gardens, Burghley*, says:—"Through your kindness I am enabled to give an opinion of Standish's New Pea, Criterion. My small packet was all sown in pots in one of the cool houses, planted out in April, withstood such a succession of cold, stormy, and frosty weather that I despaired of ever getting any Peas at all, nevertheless they braved it all and were ready for picking June 18. Criterion Pea grows from 5½ to 6 feet high; a Green Marrow of the most delicious flavour, bearing in pairs from sixteen to eighteen pods, with an average of eight Peas in each. It is the hardest and best Pea of the British Queen type."

Mr. SPEED, *The Gardens, Chatsworth*, remarks:—"It is the finest of all late Peas that I know, and is an excellent flavour and good colour when cooked."

Price, 5s. per Quart.

NEW PEA, "HARBINGER" (Laxton).

The following description is taken from the Royal Horticultural Society's report of the great trial of Peas at Chiswick, in 1872:—

"A cross between Dillistone's Early and Alpha. The plant has the habit of Dillistone's Early. Stem 2½ to 3 feet, simple, producing from seven to eight pods singly. The pods are small, rounded in form, slightly curved, very tightly filled, of a light green colour, and contain about six fair-sized Peas of a fine colour and good flavour. Ripe seed

Price, 3s. 6d. per Half-pint Packet.

CAULIFLOWER, "VEITCH'S AUTUMN GIANT."

This extremely valuable variety is perfectly distinct from any other sort. The heads are magnificent, beautifully white, large, firm, and compact, and being thoroughly protected by the foliage, remain longer fit for use than any other kind.

Price, 1s. 6d. per Packet.

VEITCH'S SELF-PROTECTING AUTUMN BROCCOLI.

A very valuable Broccoli for autumn and early winter use. The plant is of robust but upright growth, and the heads, which are beautifully white, firm and compact, are thoroughly protected by the foliage, and remain a long time fit for use. It will be found extremely valuable as a succession to our Autumn Giant Cauliflower, which has met with so much approval, and is now an established favourite in all gardens.

Price, 1s. 6d. per Packet.

LETTUCE, "EARLY PARIS MARKET."

This distinct and very handsome variety of Lettuce is much used in the Paris Market Gardens. It hearts very quickly, and we believe it will prove invaluable for forcing purposes.

Price, 1s. per Packet.

small, round, blue. Sown February 23, first flower opened May 9, was in full flower May 15, slats appeared May 21, fit for use June 26. The earliest Pea in the collection, being three days earlier than Dillistone's Early, and six days earlier than Sangster's No. 1. Received a First-class Certificate."

It is also somewhat similarly described in Hogg's *Year Book* for 1873, page 87.

AQUILEGIA CALIFORNICA HYBRIDA.

This beautiful and distinct variety was raised by Mr. Douglas, Loxford Hall Gardens, and is a hybrid between *A. californica* and *A. chrysantha*. The flowers are of a large size, the centre petals being of a clear yellow colour, and forming a very effective contrast to the deep orange-red of the sepals and spurs. In habit of growth it is intermediate between the parents, and produces its lovely flowers in great profusion. It was awarded First-class Certificates by the Royal Horticultural and Royal Botanic Societies, and is a decided acquisition to this class of hardy spring-flowering plants. The *Floral Magazine* of October gives a very faithful coloured illustration of this charming variety.

Price, 1s. 6d. per Packet.

AQUILEGIA CŒRULEA HYBRIDA.

This is another very fine hybrid raised by Mr. Douglas, and is the result of a cross between *A. cœrulea* and *A. chrysantha*. It is exactly intermediate between the parents, the centre petals being clear sulphur-yellow, and the spurs and sepals a charming shade of pale blue. The flowers are large and well opened, partaking most of the character of *A. cœrulea*. The plant is perfectly hardy, and of good habit, and is an important addition to the old but pretty genus of Columbinæ.

It was awarded First-class Certificates by the Royal Horticultural and Royal Botanic Societies, and is figured in the *Floral Magazine* of August, 1877.

Price, 1s. 6d. per Packet.

KNAP HILL, WOKING, SURREY.

Vines—Vines—Vines.

B. S. WILLIAMS begs to announce that
his VINES this year are in unusually fine condition,
and are now ready for distribution.

NEW LATE-KEEPING BLACK GRAPE, "ALNWICK
SEEDLING."—This Grape was exhibited before the Fruit
Committee, South Kensington, February 6, 1876, under
the name of Clive House Seedling, a name the Committee
have since thought fit to alter. The following is the de-
scription given by the Fruit Committee:—"It is a seedling
between the Black Morocco and an unnamed variety raised at
Wortley. The bunch shown was of fair size and well shouldered,
and the berries large, oval in form, and jet black in colour, with
a thick skin. The flavour was decidedly good, partaking of the
rich sparkling flavour of the Black Morocco, but much sweeter.
It has kept well till February, and will, no doubt, keep longer
and prove a better Grape for general cultivation than the Black
Alicante." This has been awarded a First-class Certificate.
The stock offered is from the original plant. Early orders are
respectfully solicited, as the stock is limited. Price 21s. and
42s. each. For Detailed List see BULB CATALOGUE.

NEW FIG, "HARDY PROLIFIC."—The fruit of this
hardy Fig is about the medium size. Pear-shaped, rather
tapering towards the stalk. The flesh is very sweet and
luscious. It was introduced from France some few years ago,
and has proved itself perfectly hardy. It must become a
general favourite, as it is a very abundant bearer, either in pots
or in a cold house, as well as on an open wall. It also ripens
earlier than any other variety we know of. Price 10s. 6d. each.
Extra sized fruiting plants, 21s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper
Holloway, London, N.

announcing that the above for the present season is now
ready, containing complete Lists of Liliums, Narcissus, &c.;
also a selection of Terrestrial Orchids, Bamboos and Orna-
mental Grasses, Climbing Plants and Herbs; to which is
added an abridged List of Hardy Perennials adapted for
autumn planting. Post-free on application.
Hale Farm Nurseries, Tottenham, London.

The Best Hardy Bedding Plant.

CLEMATIS JACKMANNI.—Flowers rich
purple, 4 inches across, and so profuse as to completely
cover the bed. Begins to bloom in June, and continues until
severe frost. It is perfectly hardy, and the stools improve
annually. The only secret of success is a rich soil, to keep up
free growth. Strong plants in pots, 12s. per dozen; extra strong
plants, 2 years old, 18s. per dozen. Other sorts of Clematis and
Climbers in great variety. Descriptive LIST on application.
RICHARD SMITH, Nurseryman, Worcester.

From Mr. H. BENNETT, Belle Vue Crescent, Clifton, Bristol.
March 10, 1877.

"I am glad to tell you that the Hyacinths, Tulips, and
Crocus I had in the Autumn have given entire satisfaction;
the flowers are splendid."

From R. PRONVCE, Esq., Bathgate, N.B.
February 7, 1877.

"The Bulbs received from you in the Autumn have been
particularly fine; some of the Hyacinths and Tulips now in
bloom are large and beautiful, and have far exceeded any I
have had before."

THE QUEEN'S SEEDSMEN,
HIGH HOLBORN, LONDON, W.C.

Tree Ferns, Tree Ferns, Tree Ferns.
DICKSONIA ANTARCTICA—The Advertiser continues to offer the above at greatly reduced prices. All trunks carefully selected by an English gardener from the coolest districts of Tasmania, from 1 foot upwards. They are carefully dressed and packed, and put on board ships sailing direct to London. Special terms to large buyers. For particulars apply to
Mr. WALKER, 9, Mount Pleasant, Tunbridge Wells.

To the Trade.
MESSRS. LEVAVASSEUR AND SON,
NURSERYMEN, USSY, CALVADOS, FRANCE, have an immense stock of **SEEDLING FOREST TREES, Hardy, Coniferous,** and other **SHRUBS**, for transplanting and transplanted; several millions of 1-year **THORN**. Priced **CATALOGUES** may be had of
Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C.

PETER DE COCK AND COLLEMBIEN,
 The White Flower Nursery, Meiretteke, Ghent, Belgium, offer to the Trade:—
SPIRÆA JAPONICA, forcing clumps, 14s. per 100, 66 per 1000.
DEUTZIA GRACILIS, for forcing, 18s. per 100, 48 per 1000.
HELLEBORUS NIGER (Christmas Rose), for bloom, 14s. per 100, 66 per 1000.
CAMELLIAS, AZALEAS, PALMS, FERNS, &c.

MYROBALAN, or CHERRY PLUM, is the best stuff for Mending Old Fences or Making New Ones. It grows vigorously in the poorest soils, even where Whitethorn will hardly exist, and bears clipping like Whitethorn. Its stiff hard branches, and dangerous spines or thorns, effectually prevent cattle or evil-disposed persons from getting through Fences made of it. Plant from four to six in a yard. Sizes and prices on application to
EWING AND COMPANY, The Royal Norfolk Nurseries, Eaton, near Norwich.

Florists' Flowers, and Roses.
 Autumn Edition.

New varieties already on sale, magnificent, very recommendable, and much recommended:—Madame Krelage, Lord Hawke, Madame de Cazes, Roi des Jaunes, &c.
CATALOGUES are now ready, and will be sent gratis, on demand, post-paid.

Vines and Strawberries.
"Plant now to ensure a full crop of fruit next season."
FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Canes, 3s. 6d. to 5s. each, strong Fruiting ditto, 7s. 6d. to 10s. 6d. each.
Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Price, in small pots, 16s. to 20s. per 100; from the open ground, 3s. to 5s. per 100.
Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LISTS post-free, on application. Sheen Nursery, Richmond, Surrey.

W. BALL and CO. beg to offer the under-mentioned PLANTS, all of which are strong and well established:—
AURICULAS, finest mixed Alpine, in 54-pots, 4s. per dozen, 20s. per 100.
ALYSSUM SAXATILE COMPACTA, 6s. per 100.
CARNATIONS, CLOVES, and PICOTÉES, strong, in 60-pots, twelve varieties, 25s. per 100.
The Bride, Miss Joliffe, and La Belle, 18s. per dozen.
DAISY, The Bride, the finest of all Whites, 7s. 6d. per 100.
"Rob Roy, 6s. per 100.
"Giant Variegated, 6s. per 100.
"aucubifolia, fine, 7s. 6d. per 100.
MYOSOTIS DISSITIFLORA, 6s. per 100.
CANTHARUS MACROCARPA, 1s. 6d. per dozen, 20s. 6d. per 100.
PAMPAS GRASS, extra strong, 4s. per dozen, [per 100].
PANSY, Blue King, 8s. per 100.
"Cliveden Blue, 8s. per 100.
"Cliveden Purple, 8s. per 100.
"Cliveden Yellow, 6s. per 100.
"Dean's White, 6s. per 100.
PINKS, in twenty-five named varieties, in 60-pots, 25s. per 100.
PRIMROSES, double Yellow, 20s. per 100.
"single Lilac, 12s. per 100.
ROCKETS, double Purple, 2s. 6d. per dozen, 18s. per 100.
"double White, 2s. per dozen, 15s. per 100.
SILENE PENDULA COMPACTA, 2s. 6d. per dozen.
STOCKS, Scarlet Queen, 2s. per 100.
TRITOMA UVARIA, per dozen, 28s. per 100.
WALLFLOWERS, finest dark, 2s. 6d. per 100.
All the above cheaper by the 1000. Orders amounting to 20s. boxes and packing free.
The Nurseries, Bedford Road, Northampton.

VIOLETS, SWEET VIOLETS.
MARIE LOUISE, double, light blue, white centre, flowers very free and continuous from September to May.
VICTORIA REGINA, large single Violet, very fine.
WHITE CZAR, the best white.
BLANDYANUM, large double Violet.
KING OF VIOLETS, large double Violet.
REINE DES VIOLETS, large double white.
NEAPOLITAN, double lavender.
single lavender.
Strong clumps of the above 6s. per dozen, 45s. per 100, suitable for potting in 4½-inch pots, or forming beds and masses in flower gardens. Now is the time to plant to ensure flowers all winter and spring.
BELLE DE CHATENAY, new double white, 1s. 6d. each.
PATRIE, new double blue, very free flowering, 1s. each.
One small plant of the ten varieties free by post 5s. 6d. Trade price on application.
FREDERICK PERKINS, Nurseryman, Regent Street, Leamington.

For Present Planting or Sowing.
CABBAGE PLANTS.—Gee's Superior Early Enfield Market, Drumhead, and Thousand-headed, all at 1s. per 100; Purple Sprouting BROCCOLI, and BRUSSELS SPROUTS, 1s. per 100; Winter LETTUCE PLANTS, Brown Cos and Hardy Green, at 7s. 6d. per 100. Terms cash with order. Gee's noted stocks of Winter ONIONS, CAULIFLOWER, CABBAGE, and all other kinds of Seeds and Plants for present use, of best quality. CATALOGUES on application to FREDK. GEE, Seed and Plant Grower, Nurseryman, &c., Biggleswade, Beds.

CHEAP OFFER.—Ozothamnus rosmarinifolius, white, useful for cut flowers; Escallonia macrantha, very fine for potting; Cotoneaster microphylla; Pyracantha, red-berried; Aristotelia Maqui, fine evergreen, with Laurel-like foliage, seldom offered; Santolina chamaecyparissus, white foliated evergreen; Lonicera aurea reticulata, Sambucus aurea variegata, admirable for town gardens; Ribes sanguinea. All the above at 2s. per dozen, 15s. per 100. Laurustinus, common, shining and black-leaved, 7s. 6d. per 100, 60s. per 1000.
WILLIAM ABRAHAM, Nurseryman, Limerick.

Astilbe (Spiræa) japonica.
F. AND A. SMITH can now offer strong blooming, well ripened clumps of the above, at moderate prices. The Nurseries, West Dulwich, S.E.

Fruit and Forest Trees, Ornamental Shrubs, SEEDS, &c.
J. SCOTT, The Royal Nurseries, Merriott, Somerset, has to offer large and fine Collections of the above, in large and small quantities, and at moderate prices; all are in excellent health and well rooted.
The "ORCHARDIST," price 3s. 6d. The best work on Fruit Trees and their cultivation in the English language.

Grape Vines.
MESSRS. OSBORN AND SONS possess this season an unusually fine stock of thoroughly healthy, stout, well-ripened Fruiting and Planting Canes of the best varieties in cultivation, including Novelties of established good repute; also a fine collection of FIGS, in pots. A Descriptive Priced CATALOGUE (inclusive of Fruits generally), free on application.
The Nurseries, Fulham, London, S.W.

This system is now being universally adopted by Her Majesty's Government, several of the leading Railway Companies, some of the principal Corporations, including the Metropolitan Board of Works, Commissioners of Sewers, and the New Winter Garden Companies throughout the country.
There is an enormous saving in the Maintenance and Repairs of Roofs on this System—say from 80 to 90 per cent.—and there is no reason why a Roof should not be as perfect in 20 years as the first week, because all the perishable Materials, such as wood, iron or paint, are completely covered by the glass from the destructive influences of the weather.
Another great recommendation is, that there is no breakage from contraction or expansion either from heat or cold, as the glass has full play in every direction. Tens of thousands of squares are broken from this cause every year. Nor is there any breakage from vibration of large Railway Roofs in heavy gales of wind, or from the passing of express or fast trains. Indeed, it is well known that a puttyed roof is never perfect in a station where express trains run through.
In adopting this system, all the everlasting expenses of repainting or reputting are completely done away with; and as it is now used by several of the Great Railway Companies, an enormous saving will be effected—it will have a considerable influence in supplying an addition to the yearly dividends.

SUMMARY OF SPECIAL ADVANTAGES.
1.—Saving of from 80 to 90 per cent. in maintenance and repairs.
2.—No breakage from contraction or expansion, from heat or frost.
3.—No breakage from vibration caused by heavy winds or passing trains.
4.—Squares of glass can be instantly replaced.
5.—The construction is very strong and durable.
6.—The glass can be put on in one-fourth the time of the old plan.
7.—No drip from condensation.
8.—Putty, cement, felt, &c., are entirely dispensed with.

THE QUEEN'S SEEDSMEN, READING

SATURDAY, NOVEMBER 10, 1877.

BONES.

THE tilling and manuring of land is pretty nearly all the assistance we can render it on the score of fertility. Drainage, shelter, fencing, and road-making, may often be dispensed with, and yet the land may yield good returns; but the effect of manuring is not to be mistaken, for it shows at a glance that land unaided by manure is deficient of one of the ingredients of fertility, although some water meadows have been fertile in the highest degree for generations without any manure beyond what the water from the limestone rock holds in solution. When bone manure was introduced into the grazing county of Chester, it produced the most marvellous effects, and we were told that this was owing to the bone manure restoring to the pasture fields what they had lost by the cheese they had been the means of making; and as this reason, or rather this nonsense, passed current, no one dared to fling down the gauntlet against it. Now the field did not produce the cheese, but only the grass on which the cheesemaking cows were fed, and as there was one link wanting to complete the evidence of the field doing what the cow did, the argument fell to the ground, for it was the grass that suffered or the ground that profited, and the bone-dust on the one hand and the cheese on the other had a missing link in the form of grass that had to be made good. Turnips were grown with bone manure, and there is nothing cheesey about them, but without that the Turnip crop too would have been deficient of one of the ingredients of fertility. The whole argument was in a nutshell, for, say they, the mother cow wanted bone-forming materials, and so did the calf before its birth as well as after, ergo, bone manure must be the right thing and in the right place, to restore the loss of ages, for the fields must have boned both cows and calves time out of mind. Who could gainsay such plausible theories?

Long grass grown under trees has little value as a fattening or even a feeding ingredient, and, on the other hand, short grass over a limestone subsoil will support stock and maintain them in good condition even when the bite is short and dry. When land has been limed for Barley we see the grain enlarged, and the sample brighter than on land not so manured. All this was well known and duly acted upon before the advent of bones, for in my time common sense—that very uncommon article—had not found out that to return animal substances to the earth was only completing the circle; and so the common adjoining my native village was occasionally made horrid by dead horses, and the bones that had whitened there for years and grown clean were used as playthings for urchins having little else movable to fall back on. But where were our newspapers in those days, and what of chemistry to aid the cause? I and eleven others subscribed for a weekly newspaper at 1s. each. The first man had only one hour allotted to the reading of the paper, and he might be seen—blacksmith that he was—"giving his bellows breath" and reading aloud to ardent listeners of what the First Napoleon was doing, or the notorious Hyder and Tippoo, telling, alas! of boncs of horse and rider, of black and white men, "in one red burial blent." Dur-

ing the long reign (sixty years) of George III. war was the leading theme, and grave-digging to bury bones out of sight must have been the way that this material was disposed of, so that in my time if a cow died she, too, was buried in a deep pit—what had been denied to thousands of well-deserving men, for I saw at Ripon a bone-house said to contain the skulls of 30,000 human beings, all bleached and dry, but how they came there did not transpire. Our guide was unable to say, but such an assemblage told too clearly that there had been a fearful reckoning one day in that quarter, and that some pious persons had gathered up the relics of the slain. I understand that these bones have been buried since. Our guide showed his proclivities for phrenology by comparing the intellectual skulls one with another, and surely never was such illustration of the science given before.

Whilst on the subject of bones, I may state that I saw the skulls of two dogs side by side—the one was highly intelligent during life, the other was a sorry cur; but what was remarkable in the skulls, the quality of the bone of the clever dog was thin, but hard and white, whilst the skull of the cur was grey, like unbleached calico, and coarse. One of those the poet must have had in view when he penned the lines:—

"In Islington there lived a dog, as many dogs there be,
Both mastiff, puppet, hound, and cur, and dogs of low degree."

It is, therefore, clear that bones vary in value for manure. Any one wishing to get information on bones should visit Sheffield, and when we see that a bone in the form of a knife-handle may be kept in good condition for fifty years without showing decay, we may conclude that for permanent manure (such as for Vine borders) nothing can equal $\frac{1}{2}$ -inch bones. I was shown a Vine border outside the vinery, where the crop was kept late, hanging on the Vines till Christmas, and this border, made of turfy loam, was fattened with bone, and the crop justified the mixture. There was nothing of the midden character about this border: all was clean and sweet, and once well made it might last half a lifetime.

I have nothing to say about the various uses that bones may be turned to—I only take a gardener's view of the subject; and let me state that there is always ample evidence of how bones behave in the earth by watching the gravedigger disinterring human bones that have lain some twenty or thirty years in the cold clay. The leg and thigh bones and the skull resist decay longer than the others, and it kept from the air there is no saying how long the solid parts of bone might last. In trenching a piece of old pasture we turned up a neat's bone, and as it was grey, but sound, I chopped it up for my Newfoundland dog, and he ate it up as soon as it was broken into pieces that he could swallow, and licked the block clean of marrow. Now I would ask what other kind of manure could at all compare with this eatable article, old enough for aught we knew to have been included in more than one nineteen-year lease.

I purposely abstain from saying anything for or against dissolved bones. They are not altogether suited to permanent manuring, where the dose, however good, cannot be repeated, as in the case of a Vine border. When one of the North Kent railways was being made I saw the navvies cutting through a bed of oysters some 6 or 7 feet thick, high and dry, and far enough away from the water where they had grown. Here was a fortune ready for the making, for every shell could be resolved into good manure, for this mollusc fortunately has its bones all outside, not to mention the kindred mussel, with the chance of pearls for the lucky finder.

Let no one be deceived with the various manures that are good enough for surface crops, as the cereals and the Turnip crop; for although

the ash-pit manure of Manchester, the sweepings of the streets, and the horsedung, oyster-shells, and lime rubbish may be excellent dressing for the crops on Chatmoss, the case is altogether different from supplying a Vine heavily laden with fruit, year by year, for a generation, such as we see on the Vine at Hampton Court, fresh and fruitful after the lapse of a long lifetime. In the warehouses in Manchester, where corduroys and the like are kept, there is a very unpleasant smell from the bone-size used in their manufacture, and this tells too clearly of the decay of the bone, for in the charnel-house at Ripon there was no offensive smell, notwithstanding the tons of bones that were stowed in it; but it must be borne in mind that the bones there were all large bones and skulls—the ribs, &c., may have been decayed long before I saw this melancholy spot.

It is a very nice point to settle the size of the bones to be used for a Vine border. If they are used too large there will be a great waste of an expensive article, and if they do not decay in some measure they will be no better than so many cracked stones; but, on the other hand, if ground to powder, or dissolved entirely, who could guarantee the permanent benefit, as well as the present, for the larger bones are always safe, but not so the smaller; and woe to him that does not calculate by weight or measure what ingredients he employs. A gentleman at Wilmslow showed me Oats, some 6 feet high and well corned, and he asked me what I reckoned a fair dose of common salt to the acre of his old grass park which he had broken up. I said $2\frac{1}{2}$ cwt. to 3 cwt. per acre would no doubt improve the crop. He replied, Yea, it would, for he had sowed 15 cwt. per acre with the best results on the fallow six weeks before sowing the Oats. Nothing was more common when guano first came on the stage than for people to kill the plants by using it too strong. I remember taking warning of this danger by seeing some French Beans watered with manure-water made with guano, and they were killed by the first dose. It used to be said that the Hampton Court Vine was fed by an old sewer in the vicinity, and the plant was thereby reckoned a gross feeder; but when the plant is left to forage for itself it may go near a gutter and benefit by the moisture, just as Melon roots have run into the water-cistern and taken no harm; yet who would treat Melons as they would a water meadow?

After all, there is perhaps no item of practical horticulture on which there is so much difference of opinion as in the case of water for Vine borders. One of our most successful growers floods the border with tepid water in the early stages of the Grape growing. Such treatment was never heard of until a few years ago, and we know right well that heat and moisture will act upon bones buried; for, if you let a cart stand only one night laden with bones of the $\frac{1}{2}$ -inch size, they will heat violently, and the odour will be unbearable, thereby giving due warning that their proper place is underground, I might show the lasting character of bones embedded in the earth by the teeth and bones of extinct animals found in dens and caverns, and by bone instruments made by men of whose works no record is left.

In summing up the virtues of bones for Vine borders it is clear that there is no other article of manure so compact and so concentrated as half-inch bones certainly are, and as they occupy so small a space, the limited room inside a vinery may often suffice for the border, whereas the bulky manures from the stables, &c., soon decay, and it is no small matter to remake a Vine border, or even to patch an old one. It is something, therefore, to know that amateurs may gratify their taste for Grape growing by a moderate amount of turfy loam, and plenty of half-inch bones. In the early

stages of the growth of the Grape, before the fruit begins to ripen, tepid water, with occasionally a taste of manure in it, has been fully proved to be of good service to the roots, and the supply of manure and water are always in our own hands. *Alex. Forsyth.*

New Garden Plants.

*ADIANTUM ÆMULUM, sp. nov.**

This pretty Maidenhair was introduced by the Messrs. Veitch & Sons, of Chelsea, from Brazil, and will be welcomed by cultivators as a companion to *A. cuneatum* and *A. decorum*, two of the most generally useful of all the decorative species of this extensive and remarkably ornamental genus. Yet while it has a certain degree of resemblance to these it proves to be remarkably distinct from either. It is less rigid in habit than *A. decorum*, less drooping than *A. cuneatum*, of about equal stature, but of a bluer green colour, and with a visible tendency in the pinnules to assume an oblong rather than a wedge-shaped form, which latter, however, is fully developed in those which terminate the frond, as well as the pinnae and primary pinnules. Our subjoined illustration (fig. 114) represents only the top of a frond, but the

FIG. 114.—*ADIANTUM ÆMULUM.*

elongated oblong though oblique form of the pinnules is clearly seen even in this not very characteristic part.

The stipes is slender, about 6 inches long, and of a glossy black colour. The rachis is also slender and glossy and black, and so are the secondary and tertiary rachides, the latter being exceedingly slender and hair-like in appearance. The lamina of the frond is scarcely ovate, the lower pinnae being distinctly longest, giving the frond with its tapered apex quite a pyramidal outline; it is about 1 foot long and 7 inches broad, the pinnae set on rather widely (about 2 inches apart), spreading, with the first anterior pinnule of some six or seven pinnulets lying near or crossing the main rachis, while the first posterior pinnule of about five pinnulets is set on at some considerable distance from the other and directed outwards, so that the outline of the more perfectly developed pinnae comes to be obliquely-pyramidal, the anterior side being most developed. The lateral oblong pinnules are mostly entire on the lower and lobed on the upper or anterior side, the cuneate terminal ones have usually one lobe on each side; these lobes are notched or split about the centre, and in the sinus of this notch the circular or nearly circular sorus is developed, the two sides being brought round so as to meet at the top.

* *Adiantum æmulum*, Moore, sp. n.—Fronds slender, pyramidal, tri-subquadri-pinnate, papyraceous; pinnae distinct, obliquely pyramidal, the anterior side most developed; pinnules rhomboid or oblong, tapered to the base, the terminal ones distinctly cuneate, all sparingly lobate; sori 2-4 on each pinnule, circular or roundish-renaliform, occupying a notch at the apex of the lobes; indusium smooth entire; stipes and rachides slender, ebenous, glabrous; rhizome decumbent, slowly creeping.

The extremely graceful curving habit of this new evergreen greenhouse Fern renders it quite an acquisition as an ornamental garden plant, and it is no small recommendation to it that we are enabled to add that it is equally with *A. cuneatum* adapted for drawing-room and conservatory decoration. When exhibited at the Royal Botanic Society at one of the exhibitions of the past summer it was awarded a First-class Certificate. *T. Moore.*

HYPOXIS BAURII, Baker, in Trimen's Journ. Bot. 1876, p. 181.*

This is a very decided novelty, being the first known instance of a *Hypoxis* with a bright red flower. It is a tiny plant, resembling *H. alba* in habit, of the section with small annual tubers, but differing from most of that group by its densely pilose leaves. It was discovered by the Rev. R. Baur on the Baziya Mountains in Transkeian Kaffraria, at an elevation above sea-level of from 3500 to 4000 feet. Dried specimens were sent to Kew by Mr. MacOwan last year, from which I described it, and now the same gentleman, who has worked so diligently in the department of Cape bulbs, has sent the plant living to Herr Leichtlin, who flowered it this present summer.

Tuber small, globose, annual, about $\frac{1}{4}$ inch in diameter, crowned with copious wiry fibres adpressed to the outside of the rosette of leaves. Leaves 5 or 6 in a tuft, linear, about 2 inches long at the flowering time, $\frac{1}{2}$ - $\frac{3}{4}$ inch broad, moderately firm in texture, erect, densely clothed on both sides with ascending white hairs about half a line long. Scapes usually two to a tuft, always one-headed and bractless, densely pilose, just overtopping the leaves. Ovary clavate, $\frac{1}{2}$ inch long, densely clothed with ascending whitish bristly hairs. Limb of perianth $\frac{1}{2}$ inch long, bright red, naked inside and out, the oblong obtuse segments, all six nearly alike. Stamens very minute, the broad, oblong, bright yellow anthers with a cusp to each cell. Style very short. *f. G. Baker.*

CATTLEYA PICTURATA, n. hybr.†

This interesting hybrid is one Mr. Dominy's *vielle garde* in the establishment of Messrs. Veitch. Its acknowledged parents are *Cattleya guttata* and *intermedia*, yet do not ask about nearer details—they are not on record. I guess the first-named species was the pollen parent. "The plant has a thinner growth than *C. guttata*, always two-leaved. Its largest bulb is 22 inches high, but never so thin as that of *C. bicolor*." The inflorescence makes one immediately think of that of *Cattleya guttata*. Its flowers are of some size, standing in a rich cylindrical raceme. The colour of the blooms is pallid yellow. The petals are white at the base. The lip has the middle lacinia and the angles of the side lacinia brownish purplish. Column whitish yellow, dark in front, in some purplish behind. Pollen of the truest *Cattleya*. Impossible not to think of the beautiful *Cattleya guttata* Lowii at its sight, but this is quite distinct by its even disk of lip, quite different small tubercles standing in very conspicuous rows, also by its colour. *H. G. Rehb. f.*

TANACETUM FRUTICULOSUM, Ledeb., var. BRACTEATUM, C. B. Clarke.

Differs from the type in having the inflorescence more loosely corymbose, the one-headed peduncles often 2 inches long carrying linear bracts, several of these bracts close under the involucre, longer than the phyllaries, and appearing as an outer imperfect difform series of phyllaries.

Gurwal and Kamaon, alt. 13,000 feet, collected by Falconer, Strachey and Wietterbottom, Colonel Davison. Seeds sent to England by Dr. King from Mr. Gammie in Sikkim, and raised by Mr. J. T. Riches, at Messrs. Rollisson's, of Tooting.

Peduncles often 2 inches long, but passing by every gradation to the short peduncles of *T. fruticulosum*. Bracts on the peduncles scattered and linear, $\frac{3}{4}$ inch long, sub-acute not mucronate, densely white-hairy on both sides. Several similar bracts close round the outer phyllaries, which are (as in *T. fruticulosum*) narrow oblong obovate, scarious brown yellow on the edges, on the back sub-glabrous or sometimes with much white hair. Outer female florets of the ray few, tubular, the limb 3-lobed sub-regular. Achene cylindrical curved, the testa thin slightly inflated striate, very little produced above the seed, and not (or most obscurely only) angular. *C. B. Clarke.*

* *Hypoxis Baurii*, Baker, in Trimen's Journ. Bot. 1876, p. 181.—Tubere parvo annuo fibris copiosis coronato; foliis 5-6 productis linearibus bipollicaribus ubique dense pilosis; scapo gracili monocephalo piloso foliis longioribus; ovario clavato deesse piloso; perianthii limbi splendide rubri segmentis oblongis obtusis utrinque glabris; staminibus minutis, antheris luteis oblongo-globosis apiculatis.

† *Cattleya picturata*, n. hybr.—*C. guttata* × *intermedia*. Pseudobulbo teretiusculo tereti diphylllo; rachide elongato cylindrico multifloro; sepalis ligulatis acutis, lateralibus curvatis; tepalibus cuneato-oblongis obtusiusculis, incurvis; labello trifido; lacinia lateralibus acutangulis antorsis; lacinia media cuneato-dilatata, biloba, denticulata; carinis 5 ad 7 per discum, externis serratis, gibberibus parvis multis in disco lacinia antica. *H. G. Rehb. f.*

REV. CANON GEE ON FAMOUS TREES OF HERTFORDSHIRE.*

THE Beech is expressly said by Cæsar not to have been found in Britain, and its Welsh name, "Fawydd," is taken to be an adaptation of the Latin *Fagus*. Indeed these, our old Roman masters, are thought to have naturalised here the Chestnut, Lime, Sycamore, Box, and Laurel. But they do not lay claim to have introduced the Oak, and we may safely declare the Oak to have been English in pre-historic times. No one can doubt that it thrives well with us and takes a giant's grip of our soil. It is said that even Americans, accustomed to the giant trees of their forests, yet find an unmatched stateliness and grace in the English Oak. Our climate suits it. No one ever heard of an Oak as being affected by the severity of a winter, whatever that severity may be. We may say of the Oak that its gnarled and knotty trunk is engendered by the rigours of our Northern skies. So Kingsley says of ourselves—

"'Tis the hard grey weather
Breeds hard Englishmen."

So very long has the Oak been among us that we are scarcely aware that he seems to have had an elder half-brother; at least, that much of the oldest Oak timber in this country is not of the same kind as that now in use. What we call Oak timber now is the wood of the *Quercus pedunculata*. This has its fruit stalked and its leaves sessile. The other Oak, the

amptonshire is so confidently pronounced to be 1500 years old. We can make no experiments, you know, for ourselves in this direction, unless you would repeat the failure of the good old lady, who, having heard that a tortoise would live 100 years, bought a young specimen, that she might judge for herself. I conclude that the only approach to investigation would be to notice carefully the growth of an Oak still growing, and to calculate in what time, proportionally, an old Oak would have attained its girth, and then to allow a proportionate time for decay. Of course this growth would vary much from the influence of soil and aspect; still something may be done in this way. Our Lord-Lieutenant, a lover of trees and an observer long before I took up the subject, has given me his experience with regard to trees at Gorhambury. He summarises his conclusions as being, that an Oak increases in girth half-an-inch per annum, and a Cedar 2 inches in the same time. But in the memoranda which he kindly furnished there is a difference between the Oaks of which he gave me the measurements. I do not know what experience the poet Dryden had of trees. He most likely gives us the general opinion of his own day in laying down poetically that an Oak's duration is 900 years—

"Three centuries he grows, and three he stays,
Supreme in state, and in three more decays."

ELMS.

I string together a few remarks on other trees generally. I have spoken of Elms as foreigners, but I

FIG. 115.—THE LION OAK AT HATFIELD.

Quercus sessiliflora, has its fruit sessile and its leaves stalked. This latter is the Oak which furnished timber to some of our oldest buildings—notably to St. Alban's Abbey and to Westminster Hall. The old wood is so far unlike our modern notion of Oak timber, particularly in the absence or indistinctness of the silver grain, that it was long considered to have been Chestnut. Now, the distinction which I have just laid down seems to be recognised and to entitle this old timber to be called Oak. I may mention here that at the hospital of S. Cross, near Winchester, I myself saw Oak of a very singular, dark grain. The brother who "showed me round," told me that it was considered a speciality, and that a visitor had offered much money to be allowed to replace it. He added that the peculiar grain was commonly attributed to the way in which the wood was cut. The extreme length of each plank was only 5 feet, and it might all have been cut crossways. A natural question arises at once with regard to the Oak—viz, as to its extreme age. I mean as to the age which it would attain if left to itself, or as to the age of some patriarch of our acquaintance. I do not see how this can be ascertained except by documents, and documents will not go back as far as we desire. Granted that an Oak marks its growth by natural indications, yet when growth ceases these indications stop. Not to be irreverent, an old Oak is like an old horse with the teeth marks "gone out of his mouth," as the ostler would express it. I cannot tell upon what grounds the Salcy Forest Oak in North-

admit that they were naturalised in the times of the Heptarchy. Like the old family of Coplestone—

"They where at home
When the Conqueror came."

They have given Saxon names to many English villages, as Elmham, Elmwood, Elmsthorpe, Elmstone, Elmstead, and Elmsley. The Elm's failing is to become hollow at eighty years of age, and at that time its arms and roots both become brittle. It has a special beetle to itself called the Elm-beetle (*Scolytus destructor*), and its great value is for such position as alternate wet and dry conditions, e.g., for pumps, troughs, conduits, water-wheels, and water-gates. If the Elm be originally an immigrant, he has since become an emigrant also. Perhaps it was from his own personal connection with this country, but Philip II. of Spain planted the avenues of Madrid with English Elms. Learned men differ as to the origin of the name Wych Elm. There are three derivations proposed. 1. From the Saxon word *wich*, a village or town, as Sandwich, Middlewich, &c. This would make the Wych Elm to be "the village Elm." There is this much to be said in support of the idea, that the Wych Elm does ripen a seed; so that it may be thought to have been the earlier or more recognised Elm. 2. From the word *wych*, meaning a box or press, such having been made originally of such wood. Our modern word hutch would be a corruption of this, and *wych* is applied in old writings to the ark of the testimony, as also to provision boxes in daily use. We have in old writings "wyches for cheeses." 3. From a superstitious notion that witches frequented this tree, dancing

around it or dwelling under it. So far as I can distinguish the original orthography, it seems in favour of the second meaning, which would derive the word from *wych*, a chest or box.

BEECH.

The Beech tree peculiarly claims the neighbouring county of Bucks as its own. It gives its name to the county, as well as to the indispensable thing, book. In this county of Herts it has more variety in its way of growth than any other tree which I have observed. We see the difference not far from here. The Beech close to the Langleybury Parsonage, which seemingly has always stood out by itself, is a model of what a fully-developed tree may become. It scarcely seems to have lost a twig from the first. It was carefully protected in Mr. Whittinghall's time. The hardest thing you can say of it, is that it is too perfect to be picturesque. An artist would choose a tree more twisted and reflected. At Ashridge you may see the contrary form of elegance which a Beech will take, when crowded in its nursery, and, as the expression is, "etiolated" by too close proximity of its neighbours. Then it will run up straight as an arrow, and upright as a dart. He who does not go to see the King and Queen Beeches at Ashridge, does not deserve to sit under trees or biographers of trees. These royal trees, girthing only 11 feet or 11 feet 6 inches—the lady is the stouter—run up, I am assured, 85 feet before throwing a branch. If you journey thither, mind that you go straight to the trunk and, stand close up to the very stem. Then look at all the glory of the olive-grey, smooth, clean shaft.

LIMES.

Limes are known by their employment by all carvers, and notably by that prince of carvers, Grinling Gibbons, in the production of his choice works. It is said that the wood is not only smooth-grained and beautiful in its enduring colour of pale yellow or almost straw or creamy white, but that it is also insect-proof. I would inform any one who may lately have had a Lime blown down in the recent gale, or who, as myself, have been compelled to cut down a Lime, that it should not be sold cheap. It is worth at least 2s. a foot, as it lies, and is employed to make the sounding-boards and linings of pianos, for which its little tendency to warp makes it valuable.

ASH.

Of Ash, I will only say that Gilpin, having pronounced the Oak to be the Hercules of woods, calls the Ash the Venus. I myself always reserve the title of Lady of the Woods for the Birch. Gardeners, it seems, in some places time the planting out of their bedding stuff by the appearance of the Ash leaf, and remove this tender material when the leaves fall. It is a peculiarly tough wood, and the stoutest oar, tool-shaft, or lance-handle is always made of Ash. But it is considered a dull tree, coming out late and going off soon, and without any bright colour on its rather thin foliage.

CHESTNUT.

Chestnut, whether Horse or Spanish, should always be spelt with a "t" in the middle, in honour of its derivation from Chataigne (French) and Castanea (Latin), both of which words come from the city Castana in Pontus, whence Chestnuts first came into Europe; as Cherries came from a neighbouring town, Cerasus, now Kerasaun. I particularly admire in large Spanish Chestnut trees, as at Ashridge, the twist, as of a rife barrel, which the bark takes, giving the effect of a spiral column, and making the tree look larger than it really is. I was surprised to find one tree that I measured to be only 14 feet in circumference. And there is at Abbott's Langley a singular instance that the Horse Chestnut will take root with its branches and spring out again, as does the Banyan, thicker than where it touched the ground. The road having been raised formerly under the large Chestnut on the lawn of Langley House, this process may clearly be traced where the earth has been lifted up until the branches touched the soil. They have taken root and sprung up in renewed vigour. The interest of this tree is so great that it throws literally into the shade the Cedars on the lawn.

LARCH, ETC.

I might leave out the Larch as a member of the excluded Fir tribe, but I would like to say a

* Extracts from a paper read before the Watford Natural History Society.

few words of this tree as being a tender nursing mother or nursing father to the Oak. In the only forest of which I know anything—in the Forest of Dean—they prepare for planting, or I fear I may say sowing, Oaks by planting Larches. These spring up soon and form a screen and shelter for the more valuable seedlings. By the time that the Oak can stand alone the Larch is valuable as a pole, and is then removed, to the planter's immediate profit. So is fulfilled the saying that "Larch will buy you a horse when Oak will not buy you a saddle." Still, as Sir W. Scott says, "Plant trees, good trees," as he puts into the mouth of one of his characters, I think Dumbiedikes. "They'll aye be creeping while ye are sleeping."

Now I am at liberty to notice individual trees in Herts, famous for their own grandeur, or for their story. Even in the first division of natural grandeur I desire to make a sub-division. There are trees famous for their girth, implying age, and generally involving decay. Some of our most venerable friends are mere shells. There are others which stand erect in stalwart strength, and are solid and massive trees. Comparisons are odious; but I think we ought to do justice to the really vigorous and more natural trees, for the greater girth will always be found in those which have been polled or pollarded. I do not want you to look at a tree—as do some of my simpler neighbours, in whose minds at once rises the consideration of what it would fetch when down. "I'd be bound to say, sir, that there are four load of timber in that tree. Why, I recollect when a water-wheel at such a mill wanted a new axle-pin, master got £50 for just such a oak." No; I would deprecate so commercial a view of the glories of our country. I would rather ask you to look at a grand old Oak as Smeaton, the engineer of the existing Eddy-stone Lighthouse, studied an Oak when the third edifice had to be placed on that storm-beaten rock. Then it is said it struck him that if he could imitate the proportions of a tree which weathers every blast he might hope that his work would stand. He figured to himself a model tree with a real waist, which would encourage the waves to curl over and discharge themselves innocuously. On those lines he built, and the continuance of his erection to this day shows that his labour was not in vain. Well, we will distinguish the old knotted and gnarled patriarchs from these their worthy congeners as best we may. But applying ourselves to take only the girth of a tree we are in some indistinctness, how to measure, or how to compare measurements. At what height shall we take the girth? Shall we be bound to take it at a certain arbitrary height, though not the most favourable to the particular tree? I think not. I understand that we are to get the greatest girth that can fairly be measured, after clearing the root knobs or earth knots. This, for our own comparison, should be taken as nearly as possible at the same height in all trees. I approve of Lord Verulam's rule of thumb. He always measures a tree at the height of his own waistcoat pocket, he standing on the best side of the tree for a ground level. Do what you will trees will not oblige you by coming into a competition upon terms of exact quality. I have found two trees of which the girth of one was the greater, but it was a hollow sinuous girth, while the less tree met the tape evenly and closely on all its sides, and on that account seemed really the finer tree.

Then, what shall we lay down as our unit of fame? What size shall make a tree famous? I distrust some of the extreme measurements that are given. I have sceptical doubts as to that tree in Hatfield Park, which, according to the *Quarterly Review*, measures 48 feet in circumference. If it be the Oak called the Lion Oak (see fig. 115), that tree has been measured for me, and its measurement reported as 32 feet. [With reference to the measurement of the trees at Hatfield, see our Hatfield Supplement, published on May 9, 1874. Eds.] I myself have never been able to measure more than one tree all the way round that measured more than 30 feet in circumference. That tree was the Yew in Crowhurst churchyard, in Sussex, not in Herts. It has a door in the side, and eight persons go in, and, squeezing tight, declare that they are able to sit round it inside. I would suggest that we take 20 feet circumference as our starting-point, and that we make it our business to be on howing terms with all trees in West Herts of that girth. You need not be afraid of an inconveniently large acquaintance, while you will not be overwhelmed with everybody else's favourite tree.

(To be continued.)

VARIEGATED LEAVES.

THE question of "albication," "albinism," or the white variegation of leaves, does not appear to have been yet approached from the chemical side. In studying the composition, modes of occurrence, and physiological position of the common colouring matters of plants, I have been working at albication, in the hope of acquiring information concerning chlorophyll. My results so far seem to open up a new path of inquiry. The experiments were begun too late in the year, and under the serious disadvantage, from which much of my phyto-chemical work here suffers, of the absence of a greenhouse. Still I have obtained some striking results, which if confirmed by further analyses, and supported by the very obvious synthetical experiments which they suggest, may throw much light, and must throw some, upon the nature and production of chlorophyll.

The experiments, of which I propose now to give an abstract, were performed with three plants having their green leaves variegated with white patches, or else bearing both white and green leaves. The plants were—1, *Acer Negundo*; 2, *Hedera Helix*; 3, *Ilex Aquifolium*. The microscopic appearances were not neglected, but are purposely not alluded to here. I shall designate the plants simply as Maple, Ivy, and Holly, respectively, in this communication.

The Maple leaves were from trees in the Agricultural College Botanic Garden, and were gathered on September 17. The Holly was obtained from Messrs. Jefferies' nurseries on September 24. For the Ivy, I am indebted to Mr. Taylor, of Cirencester, a number of plants being laid under contribution, the date of collection being October 4. In every case I gathered the leaves myself, and without the intervention of knife or scissors. Weighed bottles received the specimens, so that no moisture could be lost during transit to the laboratory. It is scarcely necessary to say that every precaution was taken to gather only such leaves as could fitly be compared in age and condition of growth. The water, the combustible or volatile matter, and the ash were first of all determined. The results translated into percentages are here arranged in a tabular form:—

	Maple.		Holly.		Ivy.	
	White	Green	White	Green	White	Green
Water	82.83	72.70	74.14	62.83	78.88	66.13
Organic matter ..	15.15	24.22	23.66	35.41	18.74	31.63
Ash	2.02	3.08	2.20	2.47	2.38	2.24

The watery character of the white leaves, and their comparative poverty in combustible or so-called "organic" constituents, is very marked. It may be said, speaking broadly, that the fresh green leaves of all three plants contained one-third more solid matter than the white leaves. The mineral matter or ash, when not absolutely more abundant in the white leaves, forms a larger part of their dry matter.

The nitrogen in both Ivy and Holly was found more abundant in the dry matter of the white leaves than in that of the green; but the percentages of nitrogen found in the fresh leaves of the two plants were such as to render further analyses necessary.

The matters soluble in ether were estimated in the dried leaves of Holly and Ivy. Of these matters, including wax or fat, resin, chlorophyll, and several other organic compounds, fresh white Ivy leaves contained 1.29 per cent., the green giving 3.27 per cent. Similarly white Holly leaves contained 1.75 per cent., and green Holly, 2.54 per cent.

But the most remarkable differences in composition between white and green leaves were noticed on submitting the ashes of the several plants to quantitative analysis. The nature of the results may best be seen by the following table:—

Percentage Composition of Ash of

	Maple.		Holly.		Ivy.	
	White	Green	White	Green	White	Green
Potash	45.05	12.61	35.30	16.22	47.20	17.91
Lime	10.89	39.93	21.50	34.43	12.92	48.55
Magnesia .. .	3.95	4.75	3.23	2.43	1.11	1.04
Ferric oxide ..	(?)	(?)	3.11	3.11	2.62	2.31
Phosphorus pentoxide ..	14.57	8.80	9.51	7.29	10.68	3.87

Although the above figures will require some correction (owing to the carbon dioxide of the various ashes not having been deducted); and although several important ash constituents, such as chlorine and sulphur trioxide, have yet to be taken into account before a final judgment can be formed, yet these percentages already teach us a good deal. In the ash of all three plants there is the same kind of difference between the white and green parts. In the ash of the white parts potash abounds, and in the ash of the green parts lime; while in the ash of the white parts there is invariably a higher proportion of phosphates than in that of the green. There is, however, no indication that the presence of chlorophyll in the green parts involves a higher proportion of iron. On the whole, the composition of the ash, as of the organic part of these plants, suggests a comparison of the white parts with the younger and more active parts of ordinary plants, while the green parts resemble the more mature organs. At present, further deductions would be hazardous, but a series of synthetical experiments on variegated plants is at once suggested by the foregoing analyses, and by the observation that, in some calcareous soils, many variegated plants quickly revert to their normal green condition. I hope before long to report the results of growing variegated plants in soils nearly destitute of lime, but abundantly supplied with potash salts, and phosphates. A. H. Church, Royal Agricultural College, Cirencester.

SELF-FERTILISATION OF PLANTS.

THE Rev. George Henslow read a paper on the above subject at the meeting of the Linnean Society on November 1. Commencing by expressing his gratitude to Mr. Darwin for the great assistance derived from that author's works, he, however, took exception to his phrase "evil effects of" self-fertilisation; for, although such may have appeared to him to have occurred in the case of some of his cultivated plants, yet the object of the paper was to show that self-fertilisation was a great principle in Nature; that plants naturally so raised are as healthy as any others; that innumerable adaptive contrivances are to be found facilitating self-fertilisation—and it must be remembered that setting seed is the sole "end" which can be legitimately recognised in plant life—that such plants are the most widely dispersed and are in every way "the best fitted to survive in the struggle for life."

After detailing the nature of the observations which induced the belief of any plants being specially adapted for self-fertilisation, the author enumerated the chief facts connected with it. As these have, in a modified form, appeared in the *Gardeners' Chronicle* this year, it will not be necessary to reproduce them. The remainder of the paper consisted of an exposition in detail of each of these facts; several are deduced from Mr. Darwin's works, but the section on special adaptations consists of an elaborate account of plants taken from nearly every British order which are self-fertilising, and some of which gave opportunity for the author to advance theories of plant life. For example, *Fumaria officinalis*. The three anthers of each group of stamens form a three-sided box, into which the horn-like stigma is thrust, and thus becomes pollinated. The pollen grains are numerous, but only set one seed. This plant, therefore, illustrates a principle advanced by the author, that all inconspicuous self-fertilising flowers are degradations, in the sense of being more advanced states of differentiation, but involving a reversion to self-fertilisation. In many such plants the stamens are reduced in number, though the full number is often retained, while in *Scleranthus* they vary from ten to one, yet only one seed is set. Hence the author was led to controvert Mr. Dyer's views that cleistogamous flowers are primitive forms, by showing that transitions occur between these and the usual states; and he stated as his belief that probably no primitive forms whatever exist; that all the *Monochlamydeæ* and still more *Achlamydeous Angiosperms* are degradations and not primitive types.

Viola tricolor v. arvensis served as a text for what the author called individual adaptability. Dr H. Müller has shown how this and several other plants are "dimorphic" in that, while one form is conspicuous and adapted for intercrossing, another by a slight modification becomes self-fertilising. The author found an instance where a placentiferous process grew from the style and projected from the orifice of the "head"; and in a plant of the con-

spicuous form of Pansy the "lip" or "tongue," as he preferred to call it, was so long and recurved as to "lick up" the pollen grains from the petal in front of it upon which they had fallen.

Several facts such as these have led the author to believe that plants have an individual adaptability, and can assume certain structures which perhaps may never be found again. These, and the fact that so many genera, while possessing species with flowers adapted for intercrossing yet had others habitually self-fertilised, led him to regard the acquirement of the property of self-fertilisation as a source of the origin of many species as now existing.

Capsella bursa-pastoris, or Shepherd's Purse, illustrated another feature. Not only are small flowered Cruciferae habitually self-fertilised, but may be recognised by having a globular stigma instead of a lobed one. Moreover, by tracing the development of the floral whorls of plants from nearly every order that there are marked differences in the respective rates of growth of the corolla, stamens, and pistil which are self-fertilised and those which are intercrossed. In the case of the former the pistil grows either at an equal rate as the stamens or much faster, and so matures its stigma slightly before or simultaneously with the anthers; whereas in proterandrous flowers the pistil lags behind, and is often a long time immature, while the stamens and after them the corolla have arrived at maturity.

Salvia clandestina furnished another instance of self-fertility, for whereas in large-flowered species the anther-cells are adapted to strike the back of a bee on entering the flower, in this species the stigmatic branches are much elongated, and coil back between the anther-cells.

Pinguicula lusitanica does the same — the stigmatic lobe plunges itself into the upturned gaping anther-cells.

With reference to the wide dispersion of self-fertilising flowers the author had examined a great many floras, and found that those British plants which are most widely scattered over the world are self-fertilising forms, and that if they had conspicuous allies these were not to be found. Thus *Stellaria media* is widely dispersed, but *S. holostea* nowhere; *Malva rotundifolia* is diffused, but *M. moschata* and *M. sylvestris* nowhere, &c.

The inference deducible is that if the conspicuous forms have migrated they have died out from want of the visits of insects. Such is negative evidence, while there is the positive evidence that self-fertilising forms can establish themselves, thus proving that they are the "best fitted to survive in the struggle for life."

REMINISCENCES OF COUNTY WICKLOW.

HAVING had the pleasure of spending a short time in the "Green Isle," and particularly in the above-named locality, it may interest some of the readers of the *Gardeners' Chronicle* who have not had the same opportunity if I mention a few points of interest which struck me as worthy of note.

Arriving at Kingstown I took the train to Bray—the Brighton of Ireland—and it proved to be a very interesting ride, the road skirting the seashore nearly all the distance, passing Dalkey Island on the left, about a mile from the land, and Killiney, dotted all over with its well-to-do-looking residences. Having reached Bray, I found on enquiry that Killruddery, the fine estate belonging to the Earl of Meath, was about two miles distant, and made up my mind at once to walk there, but I soon found that they were Irish miles. This fine domain is extensive and well wooded, comprising hill and dale, and containing some very fine trees, particularly of *Quercus ilex* and the true Highland Pine, the finest examples of the kind, indeed, that I had seen. The contrast between those two fine evergreens and the rich autumn tints of the Oak, Elm, Beech, Lime, and Chestnut was magnificent. The pleasure-ground, as well as the flower-garden, is extensive. The latter is rich in geometrical designs, but having a prevailing fault—that of crowding in too many beds—they lose their individuality. The bedding was, however, very well done, and much credit is due to Lady Meath for the excellent taste displayed by her, and to Mr. Moore for the able manner in which he has carried out her ideas. Mr. Moore is not unknown to fame, having filled some first-class places in England, notably Alton Towers and Belton;

and, if I mistake not, he was one of the first to make a success of keeping Grapes in bottles of water.

As carpet-bedding is rather in my way, I was pleased to see the quiet way in which it is establishing itself in Ireland. The best examples seen were here at Killruddery, but I have grounds for believing that this style of bedding will be carried out much more extensively next season at Powerscourt, and other places of importance. It is surprising to see how fertile the country is: even in the woods the common Ferns grow out of character; for instance, *Atbyrium Filix-foemina*, *Lastrea Filix-mas*, and *Lastrea dilatata* are more like groves of short-stemmed Dicksonias. From the mild and moist climate of the country one is not surprised to see unusually fine specimens of plants and trees. At Killruddery the New Zealand Flax, *Phormium tenax*, is 12 feet in diameter, and of *Dracæna australis* there are fine plants receiving no protection during the winter.

Passing on to Holybrooke, the residence of Sir George Hudson, Bart., the same richness of growth was seen. The finer kinds of Fuchsias were growing in beds as we grow Rhododendrons in England, and the robust character they acquire makes them unrecognisable as the same kinds we see grown in pots. The finest specimen of the Ilex Oak I have seen is at Holybrooke; unfortunately I have not the dimensions, but it would be interesting if Mr. Byrne, Sir George's gardener, would give the particulars. Some of the newer kinds of Conifers are thriving, and will some day vie with the fine old Highland Pines for the supremacy they now enjoy. Two stems of *Lilium giganteum*, one with thirteen and the other with seventeen seed-pods, showed how fine they must have been. How beautiful the Escallonias are when seen as they are here and at other places in Ireland—the varieties *montevidensis*, *macrantha*, and others; here also the annual *Calceolaria pinnata* has found itself a home, springing up year after year in the border, and very pretty it is. In the conservatory was a singularly pretty pillar plant, an *Aristolochia* with smooth shining rather small leaves, with flowers like those of *A. sypho*; this plant seeds very freely, bearing pods from 3 to 4 inches in length.

To visit Charleville, the seat of Viscount Monk, a real Irish car was brought into requisition, and from Bray we took the new drive made by Lord Monk some years ago, which runs parallel to the River Dargle, but at a considerable altitude. This is one of the most beautiful drives possible, the steep banks on both sides of the river being well wooded, and every now and then rocks are seen projecting up and beyond the trees. Then again you look down upon the stream with its large boulders and sharp projections, leaving no doubt upon the mind but that the "stream runs fast." Leaving this new drive, and entering the more private domain, we find ourselves in a well-wooded park of some extent, and soon we are introduced to one of the best possible kept lawns, which is well furnished with many fine specimens of *Wellingtonias*, *Deodars*, &c. Here is a fine avenue of the *Cedrus Deodara* and another of grand plants of Irish Yew. Charleville is great in hedges, and they are well kept. I don't admire hedges without a use or purpose; it appears to be the fashion in Ireland. Flower gardening is done by Mr. Douglas, the gardener, with much taste, but the effect is lost in the hedge compartments. Every department was in excellent order. Alterations were being made to the Vine borders, which will no doubt enable Mr. Douglas to show his skill in that line to great advantage.

Remounting our car we soon find ourselves at Powerscourt, the princely domain of Viscount Powerscourt. Great and manifold are the works which have been undertaken here during the last ten years, and the cry is still onward!—and I believe I am not mistaken that in Mr. Penford his Lordship has a gardener who will not disgrace the work carried out before his time. A new flower garden has not long been completed, where, as I remarked in noticing carpet bedding, I believed it would be carried out on an extensive scale, and from the position of this terrace garden no better place can be found to exemplify this fashion in flower beds. It will be seen from several elevated points, and in passing from the mansion down the grand flight of steps to the lake beyond a closer inspection may be obtained. If well carried out carpet bedding is more effective at a distance, and will bear a closer scrutiny than any other system of bedding. Arriving at the lake, the care with which the banks and the ravine beyond have been planted is apparent. A judicious selection of tree, shrub, and

plant has been made with the view, as it were, to blend Art with Nature—graceful weeping trees, elegant Pampas-grass and *Arundo conspicua*, *Pliorhiza tenax*, &c. By the way, *Arundo conspicua* is not nearly so much grown as it deserves, its flowering season is so much in advance of the Pampas-grass that if planted together the effect produced is extended for a much longer period. This portion of the grounds is rich with flowering shrubs. In the garden proper will be seen fine ranges of glass well stocked with flowering plants; the Peach-houses are in excellent condition, so are the vineries. In some two or three were still to be seen some grand examples of good Grape growing. The flower-bed arrangement in front of the range of glass was all that could be expected at that late season of the year. Both time and space forbid that I should write more concerning this fine place except to record the satisfaction it gave me to see the extensive use that Lord Powerscourt is making of the new Conifers in planting them in quantities on either side of the new splendid drive which conducts the visitor from Powerscourt to the Waterfall, a most romantic spot, where a sheet of water is thrown at a great height over a smooth almost perpendicular rock into a rocky bed below, from whence flows the famous Dargle. I am almost at a loss which to prefer most—the morning drive by the river-side, with its well-clothed banks, or the evening drive from the Waterfall through the rocky glen, the interstices of which were filled up with such a carpet-bed of *Furze* in flower and Heath as only Nature could produce. And were anything wanting to complete the picture it was to be found in the framework of mountains—the "great Sugar-loaf Mountain" on the one hand, and the small "Sugar-loaf" on the other, with Bray Head in the distance.

Before taking leave of the beauties of Wicklow, I cannot omit mention of a very pleasant visit made to Bellevue, an estate belonging to W. R. Latouche Esq. Here is, perhaps, one of the finest views to be seen in this or any other country. It is seen from the "Octagon-house," which is perched on the summit of the hill commanding a view of the "Glen of the Downs," an extensively wooded glen, in which the trees are as smooth as if they were clipped, owing, no doubt, to the fact of the sea breeze blowing through the glen, which is merged in the uninteresting flat district between this point and Wicklow town, which is seen in the distance. Returning from the Octagon-house, we are brought to the mansion and gardens through a fine young plantation of *Deodars*, Weeping Spruce, Austrian Pines, &c. The kitchen garden is old. There are no extensive glass erections, but a very interesting corridor, leading from the house to the conservatory. This corridor has some remarkable specimens of Myrtles, Acacias, *Ceanothus*, *Pelargoniums*, &c., planted against the back wall. The conservatory contains some finely-managed *Camellias*. The gardener, Mr. Colgan, has quite the gift of plant-growing. In an intermediate stove were excellent examples of good cultivation. On the lawn may be seen a large *Fuchsia Riccartoni*, 27 yards in circumference, and on a wall close by is a specimen of the Carob tree, covering a space 8 yards by 4 yards, and plants of *Edwardia grandiflora* and *Olea excelsa* are nearly as large.

If these remembrances of a pleasant visit interest only a few of your many readers, and induce them to record similar facts and sights, I shall consider I have not written in vain. *George Thomson, Crystal Palace, Sydenham.*

HERBS AND SIMPLES.

AT the meeting of the Worcestershire Naturalists' Field Club, held on October 25, Mr. Edwin Lees read a paper "On the Medicinal and presumed Magical Virtues of the Common English Plants." Mr. Lees said that his paper was founded on some Saxon documents in Government keeping that had been published under the sanction of the Master of the Rolls, and was entitled *Leechdom, Wortcunning, and Starcraft of Early England*. From this chronicle it appeared that in the good old times the common plants of the woods and fields were considered to be remedies for every disorder incident to the human body, and were cultivated in the Saxon herb gardens. Some of the "yarbs," as country people call them, were considered to have a very powerful influence, so that the common wood Betony was expected to cure twenty-eight different disorders, and a common saying was, "He has as many virtues as Betony." The

Vervain, now often seen growing in the vicinity of rustic habitations, was esteemed against all poisons, and even the Stinging Nettle, the Bramble of the hedges, Celandine, Borage, and Horehound would cure "infirmity of the joints," "heart-ache," and a dozen other things! Millefoil or Yarrow was good for sixteen different ailments, so if the plant remedies in the book of Saxon *Leechdom* could be relied on at the present time, there would be little necessity to consult an M.D., and the regular M.R.C.S. might look in vain for patients.

In those days, too, witchery and the evil eye were much dreaded, and elves with wicked intentions were believed to wander about at night to work malicious tricks. But there were talismanic plants that had power to upset such influences, and a salve made up of fourteen different plants, if smeared on the forehead and eyes of any nocturnal visitor, would stop his malignant efforts! It was, however, necessary to lay hold of him, which might not be so easy. But in many cases it was necessary to gather plants at particular times and with certain ceremonies, without which their efficacy could not be depended on. Thus Periwinkle had a host of virtues and good qualities ascribed to it, and among other things it was said in the Saxon *Leechdom Book*—"If thou hast this Wort with thee thou shalt be prosperous in thy doings, and ever acceptable." Mr. Lees humorously remarked that to test this, at the last meeting of the Club he had stuffed some branches of Periwinkle in his hat, but forgot that he ought to have gathered it when the moon was either nine, eleven, or thirteen nights old. Unfortunately neglecting this, the Periwinkle not only proved useless, but a gust of wind at night blew off his hat in crossing the railway bridge at Stourbridge, and in the darkness it could not anywhere be found.

After giving numerous amusing instances of the supposed power of plants in former times, and notices of the village herbalists and doctresses that then were in vogue, ever ready with their plant decoctions and sage counsels, he instanced the popularity of Culpepper's *Herbal* only a few years since, as a proof of the credulity of people in general as to the wonderful qualities of the commonest weeds, all of which were commendable for something. Even yet herbalists made a living by gathering Tansy, Wormwood, Centaury, Sanicle, and other plants, and although the commoner vegetable remedies were excluded from the Pharmacopœia in the present day as being of little or no efficacy, perhaps our incredulity in the herbs so valued in olden times may be carried too far. Many plants had been introduced by the various tribes that had invaded Britain, and these, nurtured and esteemed for a time but afterwards neglected, yet remained in the vicinity of civilisation, and were recognised as "domestic plants." The late Mr. George Jordan, long a valued member of the Club, and who lived to be near ninety years of age, used to relate that in the days of his youth most of the common people lived upon salted viands all through the winter, and there was thus a necessity in the spring to imbibe diet-drinks as they were called, made from decoctions of various plants, to purify the blood and prevent scurvy. This necessity had passed away, but still botanists and lovers of Nature were curious to gather up the plant lore of the past, and like industrious bees extract instruction from every opening flower, and find something worth notice even in the humblest weed.

POTASH AS VINE MANURE.

POTASH as a manure for Vines has been recommended by more than one good Grape grower, and with good reason, as I intend to show farther on. But the chief end for which this paper is written, is to call attention to the statements concerning this which appeared lately in a contemporary. The article to which I refer pointed out the use of potash as a manure for the Grape Vine, and the writer gave his method of supplying potash to his Vine borders. I wish to say something on this, as his method is almost sure to lead into error any who may have reason to suppose that potash has been deficient in their borders, and are intending to follow the writer's way of supplying it. The method was to save all the garden rubbish and burn it, and apply the ash to the Vine borders with the idea of supplying potash in sufficient percentage to make matters right.

In order to understand the case fully, we must take into our consideration how Vine borders are made, and

what they are chiefly manured with. The manner of making we may pass over, as that is familiar enough to every gardener, with the remark that most good loams contain a far greater percentage of lime than of potash, although potash is present in all good loams. This percentage of lime is farther augmented, in a majority of cases, by the addition of lime rubbish, and often enough a sprinkling of quick-lime. Then bones are almost always added, and these furnish phosphate of lime and magnesia. Sometimes horse-droppings are added, and sometimes a little common stable-yard manure, and in this case the addition of mineral matter is chiefly lime, silica, and magnesia, with a little potash. This is the food generally given to a plant which wants potash in a greater percentage than lime to supply its wants as regards mineral food. And then when people get these facts placed before them, and see that potash is what is deficient, then we have those who profess to lead telling them to manure with the ashes of garden rubbish.

Garden rubbish is a somewhat vague definition of what to burn in order to get proper ashes for Vine manure, but it most likely arises from the erroneous idea so prevalent among people, who really do not know anything about the matter, that all wood-ashes whatever consist chiefly of potash. And this is the error which I wish to point out. I will enumerate some kinds of "garden rubbish," of the ashes of which I am able to give the analysis by such eminent authorities as Liebig, &c. :—Old Pea-stakes, generally either of Beech or Fir wood; orchard thinnings or prunings, chiefly of Apples; Pea-straw, Potato-tops, Asparagus-tops, Brackens (where used); Mustard (garden), Spinach, &c.

Ash of

Beech-wood.	Fir-wood.	Apple-wood.	Pea-straw.	Potato-tops.
Lime (carbonate) .. 49.54	50.94	63.60	47.81	43.63
Potash (carbonate) .. 11.72	11.30	19.24	7.30	2.35
Soda (carbonate) .. 12.37	—	—	—	—
Potash (sulphate) .. 3.49	—	—	—	—

Asparagus-tops	Brackens.	Mustard.	Spinach.
Lime (carb.) .. —	24.80	20.81	13.11
Potash (sulph.) 6.01	0.70	9.80	9.69
Soda 34.21	—	—	34.96
	Silica .. 73.00	—	—

A glance at this table shows that potash, which we have seen to be most wanted, is very subordinate to lime, which is present in too great percentage without the addition of such ashes of garden rubbish. This table should demonstrate how unsatisfactory such general directions are, and how very apt to mislead those who have no such data to guide them. To compare with this table I give another, to show the wants of the Vine as regards potash and lime :—

	Ash of		
	Vine-wood.	Grape juice.	Grape must.
Potash .. 37.48	76.30	62.74	
Lime .. 43.68	6.00	5.11	
	Grape skins. Grape stones.		
	Potash 46.89	20.45	
Lime 21.73	35.57		

It will thus be seen that potash and lime should be supplied in nearly equal quantities in the food afforded, and this is not done in the usual way in which borders are made up, nor does the application of the ashes of garden rubbish make up the deficiency, but rather add to the already preponderating percentage of lime when such articles as we have enumerated are employed to furnish the ash. I have only given a few, and, if necessary, could double the number of different plants which yield more lime than potash in their ash, but I merely mention the names of a few so that they may be avoided for such a purpose unless the lime they contain is ignored for the sake of the potash they yield. I may here say that the potash in all ashes readily dissolves in water, while lime in the state of carbonate is insoluble, and by taking advantage of this fact a manure-water made from ashes will be rich in potash with no lime if the liquid thus made be drawn off clear. When the ashes are added bodily to the border the carbonic acid evolved by the decaying organic matter present will convert the carbonate of lime into the bicarbonate, in which state it is easily dissolved. Some waters (hard ones) have a percentage of bicarbonate of lime; if a little

lime-water be added to such all the lime present becomes the insoluble carbonate, and if this is allowed to sink to the bottom and the clear water drawn off, it is freed of lime and rendered soft.

Plants (or parts of plants) yielding more lime than potash in their ash, in addition to those already given :—Broccoli leaves, Centaurea (Bluebottle), Cabbage leaves, Elder bark, Elm, wood and bark; Flag (sweet), Flax, Hops, Lucerne, Linseed (equal), Moss (Sphagnum palustre), Madder-root, Orange tree, Pines, Parsnips, Sabine wood (scarcely a trace of potash), bark of Lime tree (old mats), Thistles, Ground Pea, Onion stalks. A few of these can only find their way to the garden-heap occasionally, and in limited quantities, but some of them are always present in quantity. It will thus be seen that "the ashes of garden rubbish" is no true guide to what we are really giving. It seems to me that the proper thing to give as manure to an established Vine border is just what is removed from the Vines annually. The leaves and prunings constitute the greatest amount of ash-yielding matter thus removed, and the collecting of these and reducing them to ashes and putting this on the borders would replace exactly what is thus removed. The only other item, and which cannot thus be replaced, is the fruit; and the amount of potash removed by this means is almost infinitesimally small, something less than 6 lb. in a ton of Grapes, and there need be little difficulty in replacing this. For instance, 1 ton of cow-urine furnishes over 70 lb. of potash salts, or a great deal more potash than is wanted in a ton of Grapes.

Perhaps it may not be out of place here to point out the fact that most guanos furnish phosphate of lime to a greater extent a good way than potash salts generally. The percentage of the lime phosphate is about 30 per cent. against 5 per cent. of alkaline salts. Those who deal greatly in guano-water for their Vines may note this. At the same time I may point out that there are certain plants and portions of plants whose ash is so rich in potash, that those who have a mind to supply the substance in that way may be none the worse for having a selection of "rubbish," which could be kept separate for that purpose. I will tabulate a few of these :—

	Ash of		
	Artichoke (roots), Jerusalem.	Beetroot tops.	Gooseberry.
Potash	44.5	21.26	8.63
Lime	2.3	—	—
	Beetroot. Hemlock. Gooseberry.		
	Potash .. 39.0	12.80	38.65
Lime	7.0	8.39	12.20
	Lettuce. Leeks. Onions (Portugal).		
	Potash .. 46.1	33.115	39.005
Lime	6.05	9.955	9.326
	Cucumbers. Celery. Cauliflowers.		
	Potash .. 34.39	22.07	34.39
Lime	6.31	13.11	2.96
	Bean straw.		
	Potash salts	—	35.36
Lime salts	—	—	45.00

And perhaps a few more; but these are quite enough to illustrate my purpose in this instance, and may enable not a few to guide their actions according to method instead of in a vague way, which they themselves are unable to account for. A. H.

SPOUTED WALLS FOR FRUIT TREES.

YOUR correspondent, Mr. T. Shingles, writing from Tortworth, drew attention to the failure at that place of Peach trees which had had the advantage of a wide coping of glass, and which during the time of the disastrous days in spring had an additional covering of netting suspended from the glass coping. I am glad Mr. Shingles spoke out in this way, for if those glass copings are found to be of no practical value there is no use in one being at the expense of putting them up; but I should think a good deal of this glass coping or shading has lately been put up about the country. Perhaps others will be kind enough to give their experience.

Without glass coping or covering of any sort my outdoor Peaches have this year been marvellously successful. The fruit were plentiful on the trees, and excellent. The varieties are Stirling Castle, Belle Beauce, and Padley's Seedling. Some years ago these trees suffered severely from what I thought to be drip from the coping of rain or sleet freezing on the thicker branches of the trees. The trees on many parts were denuded of their bark, and for a time I was wickered enough to think that some mis-

chievous youth had been climbing up the branches on to the top of the wall. This idea could not long hold good, for an open door close by obviated any necessity for climbing. I therefore came to the conclusion that the injury to the bark was sustained by the effects of the freezing influence of drip from the sandstone coping. To remedy this supposed evil I had the wall spouted, and have not since observed any fresh injury to the bark, and the injured portions are now healing nicely over by a covering of healthy bark.

These trees are maintained in health by scrupulous attention to the cleanliness of their leaves in early spring, just at the time when the blossom is in full bloom and the leaf-buds partly expanded. This is the time when the greenfly does its best to effect a lodgment, and a little timely administration of tobacco-water at that stage does much to ensure success and

wind so disturbed the leaves as to prevent him from obtaining a plate sufficiently clear, but, such as they are, I send three of them. By examining them with the aid of a reading glass you will find them closely dotted all over with fruit, and alike from the top of the tree to the lower branches. I might easily dot the fruit all over with a red pencil, which would make them more visible, but then it might be said that I dotted where there was no fruit, so I prefer sending you the plates just as they were taken.

The bees which did such good work in my early Peach-house were moved to the second, third, and fourth houses—not because I thought the blossoms at that later period of the year required their assistance, but their having been agitated so early in the year, and evidently making good use of their opportunity, I resolved they should have the benefit of a run all through. The hive, which was not one of the strongest

GREENHOUSE HARD-WOODED PLANTS.

(Concluded from p. 558)

An old practice in the potting of Heaths was to elevate the balls so high in the pots that little room was left for water; this was done with a view to keep the collar of the plants sufficiently dry, which is essential, but it can be effected equally well by keeping it somewhat higher than the rest of the surface of the ball, leaving this sloping gradually from the centre to within a little distance of the sides of the pot; by this means the whole can be kept enough below the rim of the pot to allow proper space for watering. Three-quarters of an inch is not too much for plants in 8-inch or 9-inch pots. Studiously avoid light potting; in all cases ram the new soil so as to

FIG. 116.—BELLE BEAUCE PEACH TREE, GROWN ON THE SEYMOUR SYSTEM, BY MR. MILLER, AT COMBE ABBEY.

comfort in Peach management for the remainder of the season, and so on for the healthy maturation of plump buds and shoots for the next. The Peach, no doubt, delights, in this country, in being placed against a warm wall, but by doing so we place it in some respects in a most unnatural position—1st, the warmth of the position invites the breeding and maturing of all the insects that Peach trees are heir to; there is first the greenfly, second the spider, and third brown-scale, and even thrips. All these must be fought with and effectually driven off and kept off, far beyond the boundaries of either the Yaotra or the Lom. There is again in this artificial position the drip from the coping; this downpour on the wood and leaves of the trees is unnatural, and should be obviated by the spouting of the eaves of the coping. Other manipulations carefully and timely attended to will all tend to produce healthy and handsome trees, and fruit also in the season worthy of the artist.

Unfortunately, the day the photographer came the

to begin with, swarmed in June, at which time I put on, and have lately taken away a very nice super of honey. One coincidence of the presence of the bees in the early house was a crop from a small Oldenburg Nectarine of over twelve dozen splendid fruits. From the same tree I never before could gather more than a dozen. This tree I had often thought of replacing by another, but on account of its good behaviour this year I have granted it a respite, and hope that, by the assistance of the bees during other years, it will keep faith with me.

In early houses I consider it is absolutely necessary to assist Nature in the fertilising of the blossoms, and having such good results by calling in the aid of bees I look upon the "finger and thumb" process as a practice obsolete—a thing of the past. *W. Miller, Combe Abbey Gardens.* [The trees alluded to are, we can testify from our own observation, beautiful specimens of training, well furnished to the bottom, and, as the photographs show, bore an excellent and an even crop throughout. EDS.]

make it as close as that contained in the old ball. If this is not done, in giving water afterwards it will pass down the sides through the new material, leaving the centre in which the roots exist so dry as to cause death or disease.

After potting keep the house a little closer than usual for a few weeks, giving no side air; and, if the weather is bright and dry, sprinkle the surface on which they stand, so as to counteract the loss of moisture from the leaves given off by evaporation. It may be well to state here that although they are essentially air-loving plants, and are able to bear a freer admission in direct contact with them than the generality of the subjects grown in greenhouses, still during the time the cutting March winds are blowing side air should be admitted to the house with caution—even to such as do not receive a shift at this time, or the leaves will most likely be injured to an extent that will cause them to become of an unhealthy bronzy colour, from which they rarely recover, dying and falling off before their allotted time, which, as a

matter of course, is alike detrimental to health and appearance. As soon as they are potted all the stronger branches should be bent well down in a horizontal position, close to the rims of the pots; if this is not attended to whilst the plants are young the omission can never afterwards be remedied, as the shoots of many sorts get too strong to bend, and the requisite outline cannot be preserved, as the strong growths, even if repeatedly stopped, have such a tendency to take the lead in an upward direction that the weaker branches are starved and ultimately die off, leaving the plants naked and unsightly at the base, for which there is no remedy, as few Heaths will bear cutting back far into the old wood. Whatever stopping is required in the shoots should be done at this stage, as the object with this young stock is to lay the foundation of future shapely specimens rather than any consideration for the bloom they make this first season.

In a few weeks the roots will have begun to enter the new soil, when more air may be given. Each plant must now be daily looked over so as to ascertain if it requires water, continuing this all through the summer. Many fail to grow these plants satisfactorily through erroneous impressions entertained as to the water they need. It is generally understood that if a Heath flags through want of water death is likely to follow, and from this impression those in charge are often induced to give water before it is absolutely needed. This is equally certain to bring about an unhealthy state, fatal in its consequences. Taking the family collectively, they require the soil to get drier before water is applied than other plants, and the harder-wooded and slower-growing the variety, the more necessary is it to treat in this way. But in all cases when water is given enough should be applied to moisten the whole of the soil, but not to saturate it, as from the extremely fine delicate nature of the roots they cannot bear any excess. As a matter of course the more vigorous the condition the more necessary it is to see they do not get too dry before watering. The same holds good in the case of the softest free-growing kinds, and with all the soil during the summer season should never be allowed to get so dry as in the winter when comparatively little growth is in progress.

Through the summer provision should be made for standing the pots on a bed of ashes in the house; this applies to all excepting the soft-wooded winter-flowering kinds, which should go out-of-doors by midsummer. If only a few inches in thickness it will be much more conducive to free growth than bare shelves; the moisture which the ashes contain softens the air and makes it much more genial to the plants during the growing season, at which time it should be daily freely sprinkled with the syringe. The plants themselves should not be syringed—for although this promotes growth, it makes them so soft as to render them more liable to the attacks of mildew. Neither should they be shaded in sunny weather, or the effect will be similar. They should be kept under glass until the beginning of August, at which time they ought to be stood out in the open air on a bed of ashes sufficiently thick to exclude worms, letting them stand close enough, so that each plant will screen the pot of the one behind it from the sun during the middle of the day. The direct action of the sun on the pots has the effect of injuring the roots, that with a healthy plant lay in quantities against the inner surface. Should there be an appearance of drenching rains, lay them down on their sides. Take them in about the middle of September, for, if left out until the nights are frosty, the young growth will suffer.

Winter as before in a light airy situation, attending to their wants as advised for the preceding season. If all has gone well they will need more root-room the following spring, giving a 3 or 4-inch shift in the case of those with plenty of roots, and less to such as are not so strong. Most of the plants will flower during the spring, summer, or autumn, according to their season of blooming, and make nice decorative subjects; but if used in this way they must not be put in dark houses, or crowded amongst other plants, or they will suffer thereby. Where it is deemed more desirable to grow them on quickly to a larger size, then it will be well to pinch out the points of the shoots about the beginning of February; this will cause them to break out bushy, to further assist which tie out the strongest shoots, as advised in the spring previous, treating through the summer and following winter as before. They will by this have formed nice compact

plants, and should be let to bloom, after which the freest growing kinds ought to have their shoots shortened back to about two-thirds of their length; but all the slowest growers should merely have their flowers picked off as soon as they have faded, not allowing these to remain on to form seed, which has a weakening influence. They should be treated in this way all through their existence, for, if left to seed, it will not only have the effect of causing them to flower later the ensuing year, but also reduce the quality and strength of their blooms.

Staking and tying should be carried out each winter, when the plants are most at rest. Use no more sticks than necessary to hold them in their proper position. The weakest wooded varieties will need the most support, but in all cases do not put the stakes down deeper into the soil than requisite, as they cannot be got in without more or less breaking the roots. When the plants are only wanted for home decoration fewer sticks will suffice than when they have to be moved about considerable distances for exhibition, in which case they must have their shoots better secured.

The subsequent treatment year after year will be much of a routine character, in accordance with the directions already given, using the potting soil in a more lumpy state as the plants get bigger, and always letting them have enough root-room as they require it, for if ever allowed to become pot-bound they are liable to die when shifted. As the plants get old and in pots as large as deemed desirable, they may with advantage be assisted with weak manure-water during the spring and summer; and when they occupy pots of considerable size it will be necessary at the time they are turned out to harden in the summer to put a piece of old mat or canvas round the pots, so as to break the force of the sun.

There are a few kinds that require especial treatment. The yellow-flowered, drooping-habited *E. depressa* should be stood out in the full sun from the beginning of June until autumn, or it will not set its flowers freely. This sort does not usually bloom well two seasons together. One of the finest Heaths in cultivation, *E. Cavendishiana*, will bear after flowering placing in a comparatively warm, close, moist atmosphere, such as suits *Azaleas*, whilst making their growth—previous to which, when its gets too tall, its branches may be cut much closer than most other sorts will do with; it will bear their being shortened in to the extent of one-third, but after it has made growth in such a structure it should be exposed to the open air for a month before autumn, or it will be too soft to winter well. The winter flowering kinds, of which *E. hymnalis* may be taken as a representative, should after blooming have their strong shoots cut freely back, or they will soon get too tall. The spring flowering *E. propendens* ought to be treated similarly.

The following are a selection of the best kinds that will give a succession of flower over a great portion of the year:—

<i>E. Victoria</i>	<i>E. exquisita</i>
<i>E. M'Nabiana rosea</i>	<i>E. Masoni major</i>
<i>E. Hartnelli</i>	<i>E. Lindleyana</i>
<i>E. Devoniana</i>	<i>E. amula</i>
<i>E. mutabilis</i>	<i>E. eximia superba</i>
<i>E. aristata superba</i>	<i>E. Paxtoni</i>
<i>E. Cavendishiana</i>	<i>E. Shannoni Turnbullii</i>
<i>E. depressa</i>	<i>E. insignis</i>
<i>E. Candelliana</i>	<i>E. Shannoni glabra (new)</i>
<i>E. propendens</i>	<i>E. opulenta (new)</i>
<i>E. tricolor coronata</i>	<i>E. Parmentieriana rosea</i>
<i>E. " Eppsi</i>	<i>E. Irbyana</i>
<i>E. " Wilsoni superba</i>	<i>E. Austriana</i>
<i>E. ventricosa coccinea minor</i>	<i>E. Jacksoni</i>
<i>E. " magnifica</i>	<i>E. Marnockiana</i>
<i>E. " grandiflora (Story)</i>	<i>E. retorta major</i>
<i>E. " Bothwelliana</i>	<i>E. hiemalis</i>
<i>E. obbata</i>	<i>E. Wilmoreana</i>
<i>E. ampullacea obbata</i>	<i>E. gracilis</i>
<i>E. Fairieana</i>	<i>E. " vernalis</i>

The above forty varieties are diversified in colour and form, good growers, and come into flower in something like the order in which they are named from the early spring through the summer, autumn, and winter; and, whether for exhibition or home decoration, may be relied upon as calculated to give satisfaction.

Insects—Heaths possess one great advantage over most other plants, they are little liable to the attacks of insects. Scale, both brown and white, will live upon them. In the case of a plant affected with the latter it is much better to destroy it at once than to run the chance of its being communicated to others. The brown species is less difficult to deal with, although not easy to eradicate; where present it is confined principally to the wood. It may be kept down by the use of the brush and sponge, and washing with a moderately strong solution of insecticide in the autumn, after growth is complete. *T. Baines*.

Notices of Books.

We are happy to announce the publication of a new edition of *Thompson's Gardeners' Assistant* (Blackie), under the superintendence of Mr. Thomas Moore. The old edition was for the time at which it was published the best general treatise on gardening in the language, and we are assured that no pains have been spared to bring the work up to date. Several new sections have been added relating to orchard-houses, heating, laying-out of gardens, florists' flowers, carpet-bedding, table decoration, the management of conservatory and stove plants, &c. So enlarged and improved, *Thompson's Gardeners' Assistant* forms a cyclopædia which no garden library can dispense with. We shall allude at greater length to the contents of the volume at a future time. *M. T. M.*

— We notice the publication of a second edition of *The Clematis as a Garden Flower*, by Mr. Thomas Moore and Mr. George Jackman. The former edition was a model of what a garden monograph should be. While giving sufficient clues and indication to the physiologist and botanist requiring information of a character not ordinarily desired by the cultivator, it gave a very complete account of the history, production, and culture of the numerous varieties which the skill and good fortune of the raisers had brought before the public. The introduction of these fine varieties constituted a distinct era alike in horticultural botany and ornamental gardening, and most desirable it was that its history should have been written. In this second edition many new features are introduced, in accordance with the increased knowledge which experience has given of the qualities of the several varieties and their fitness for particular work. The descriptive lists have been recast and extended so as to include the latest additions and the certificated varieties, and the volume now ends with a very useful index of species and varieties classified according to their botanical origin, and their habit of growth, flowering, &c. The *Clematis* now belts the year with flowers, with the exception (even that not always valid) of about one month. The writer of these remarks has in his own small garden began the year with *calycina* and *cirrhusa*, and followed up with *tubulosa*, *Jackmani*, and *graveolens* till *cirrhusa* again made its appearance. Alike for dressed garden, exhibition purposes, wilderness walks, and roteries and rough banks, the *Clematis* as a whole is unrivalled. Would that some enthusiasts would follow up the advice given by a writer in this journal, and plant a number of the free-growing varieties in such places as the Undercliffe in the Isle of Wight, the greensand cliffs at Folkestone and Sandgate, and hundreds of similar localities by the coast and inland. *Y.*

— M. André de Vos has republished his very useful *Énumération Méthodique des Plantes Nouvelles ou Intéressantes*, or "Enumeration of the New or Interesting Plants published or alluded to in the principal Horticultural Journals of Europe for the year 1876." M. de Vos has not confined himself to a mere list of names, but has given us a brief descriptive paragraph and a reference to the work in which the plants in question are figured and described. The arrangement is according to the natural orders. In future it is to be hoped that M. de Vos will give in addition an alphabetical index to the genera, for the sake of those who are not botanists enough to know under what order to look for a particular genus. In the meantime we can but tender our hearty acknowledgments to the author of this very serviceable enumeration.

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Azaleas.—The useful character of these plants in giving a long succession of flowers is now much better understood than it once was. There are few plants adapted to conservatory decoration that, by suitable treatment, can be made to flower over such a considerable portion of the year. Independent of the different forms of vitata, a totally distinct section undeservedly much neglected, which will bloom without forcing from September to March, there is no difficulty with a sufficient number of the ordinary varieties, in having them in from Christmas to midsummer; but neither this early nor late flowering can be accomplished except by plants that have received the requisite treatment for two or three years, so as to gradually induce a habit of blooming early or late as the case may be. Not but that plants that flowered best during the early spring may be forced to have them in bloom at the beginning of the year, or late ones, on the other hand, retarded, so as to open their flowers much later than hitherto; but to be had in early they would require the application of more heat than is consistent with the flowers standing well when open, whereas if they have been in previous years gradually brought on to open their blooms in the winter they will do so with less forcing, by which means the flowers will last much longer either on the plant or when cut—the latter a matter of great importance at the present day. In the same way plants that have previously had their flowering kept back more or less can be induced to bloom still later without being subjected to the chilling process often resorted to, and which ends in the flowers opening not more than half their natural size. Such as are wanted in bloom soon after Christmas should at once be placed in a little heat and brought on gradually. They may have a little moisture overhead by syringing once a day, but over much should not be used, as it encourages too much shoot growth, and makes the whole soft. Plants that flowered late, say up to the end of June, and have through the autumn been subjected to sufficient heat for maturing their growth and plumping up their bloom-buds will be approaching completion in this respect; they should not be removed into cooler quarters too soon, under the impression that this will have the effect of inducing a later disposition to flower. Plants with thoroughly plump, well-ripened flower-buds I have always found easier to retard late than such as had their growth stopped in a softer state. Whatever tying is required to these later plants should be finished at once; for home decoration comparatively little support is required, but there is one essential that should never be lost sight of, that is, to keep the strongest branches well tied down to the base. Plants that are somewhat earlier and have finished their growth and are wanted to bloom late should be kept as cool as possible with plenty of air on in the daytime, and also at night when there is no likelihood of frost; as a matter of course they will now require much less water, but never let the soil get so dry as is sometimes practised.

SOFT-WOODED GREENHOUSE PLANTS.—Pelargoniums.—The free early-flowered section of these plants, now so much in demand for conservatory decoration and the production of cut flowers, and which by the selection of suitable varieties and the requisite treatment can be had in bloom during the latter part of winter, must now receive every attention by being sufficiently tied out to secure sturdy growth; they must be well elevated up to the roof glass, and be subjected to a temperature a little higher than that of an ordinary greenhouse, 45° during the night will answer for them. Primulas.—There has been considerable advance in the varieties of these plants during recent years; the fine double flowered varieties of the large bloomed section, totally distinct from the old dwarf-growing, weak constituted double-flowered white forms, are a great acquisition. There are some now which are thoroughly robust strong growers, with the individual bloom-stalks sufficiently long to adapt them much better for bouquet work, with the flowers as double and almost as large as the blooms of a moderate sized double Balsam. Their propagation by cuttings no doubt makes their increase a much slower process than raising the single kinds from seed, as well as entailing a little more labour; yet nevertheless they are worth all the trouble, if only for the single fact that their flowers stand so much longer than the single ones—the vexatious disposition the blooms of which have to fall off when a few days old with the slightest touch is well known to all who have had much to do with the arrangement of cut flowers. To do them well through the winter without damping, they, in common with all the kinds, should be kept in a temperature of from 45° to 50° in the night, and close to the glass. If the corner of a small pit along with Cyclamens can be afforded them it will just meet their requirements. These last-named should now be

well attended to. Look over them carefully, to see that they are free from greenfly, which conceals itself under the leaves in a way that, unless sought for, it is not detected until much injury is done. Plants in full bloom should as they come in be removed to the conservatory, or wherever required for decorative purposes, but the main stock ought to be still kept on in the growing pit or house where they can have a temperature such as already indicated. Seedlings sown the latter part of the summer will by this time be ready for pricking out into pots or pans drained and filled with good loam to which has been added some sand and leaf-mould, also keeping these near enough to the glass to prevent the leaf-stalks being drawn up weakly. Mignonette intended for early flowering, as well as the later crop, must receive the requisite attention; such plants as are required for spring blooming should if they now show flower have it pinched out. Where the pots are well filled with roots the plants should be sufficiently supplied with manure-water to which has been added a little soot; there is nothing tends more than the latter to impart to the leaves the deep green healthy tint which adds so much to the appearance of Mignonette in pots, and without which, however full of flower, it does not look well. *T. Bates.*

FRUIT HOUSES.

PEACHES AND NECTARINES.—In the preceding Calendar upon this subject I referred to the importance of using the utmost diligence towards the extirpation of insect pests before recommencing forcing operations for the ensuing season. If such matters have had due attention, allowing an interval of a few days after the trees are dressed to allow the composition employed therein to set firmly, forcing operations may be commenced whenever desired. To have ripe Peaches and Nectarines by the middle of May next season, a gradual excitement should be permitted to take place at about the middle of the current month, in the first instance by merely closing up the house entirely at night and keeping it so whenever cold weather prevails; under other conditions give sufficient air to prevent the internal temperature ranging much higher than that which exists out-of-doors, and unless absolutely required by stress of weather, use as little fire-heat as possible during the first fortnight or three weeks, when 45° to 50° at night, 55° during daylight, and about 65° from solar aid, will amply suffice. More than this may prove to be a source of mischief, and therefore to insure success it is best avoided. A moist condition of the atmosphere will be most conducive to excite vegetation, and therefore it should be maintained by sprinkling the floors or borders in the house occasionally, and the trees at morning and afternoon. Take advantage of unsuitable weather out-of-doors for pushing forward the necessary work which remains to be done before forcing commences in later houses. By no means neglect to give a plentiful supply of water to borders which are protected from obtaining any benefit from the rainfalls, and complete as expeditiously as possible any lifting of the roots or root-pruning which still remains to be done. *G. T. Miles, Wycombe Abbey.*

CUCUMBERS.—If the demand for Cucumbers is not excessive the plants expected to yield a supply from December onwards will be greatly improved by the removal of nearly all the young fruit and male blossoms, unless, as is sometimes the case, the plants have limited room and are growing extra strong, when moderate cropping will be found the best course to follow. To produce an unlimited supply up to Christmas is no difficult task, but to continue it up to the end of March is the best test of skilful management; and assuming that heat, soil, and structure are all that can be desired, light cropping until the plants are thoroughly established will be found the stepping-stone to success. Although winter culture is by no means difficult, there are certain rules, simple in themselves, which must be followed pretty closely so long as daylight is more than counterbalanced by darkness. A minimum temperature of 70°, with a rise of 10° to 15° by day from sun-heat, and a bottom-heat of 80° to 90° should be maintained. The soil or turf, taken off thin, moderately heavy, may be used rough as it is brought home, little and often, with a liberal admixture of broken bricks and lime rubble which will admit of a free passage for roots and liquid-manure when the time for feeding arrives. Syringing the foliage, as a rule, will no longer be advantageous, but moisture must be produced by damping the beds, paths, and walls, filling up evaporating-pans, and the frequent introduction of small quantities of fresh horse-droppings. Ventilation at the top of the house on all favourable occasions, as a means of changing and sweetening the atmosphere, rather than lowering the temperature, must not be overlooked; and last, though not least, cleanliness will form an important item in the daily routine, as mildew and canker are very often fostered by a close, damp, unhealthy atmosphere. The usual remedies, as is well known, are sulphur and quicklime, but prevention being better than cure, the insertion of a few ventilating bricks on a level with the

surface of the soil, and, if practicable, opposite the return pipes, will very often render the application of these antidotes quite unnecessary; growth will be more vigorous, and, naturally, red-spider will be less troublesome. Where bottom-heat is obtained from hot-water pipes, and pot culture is closely followed, worms are seldom troublesome, but under the old system of growing the plants on dung-beds with decaying animal manure in the compost these pests increase rapidly, and very soon render the soil unfit for maintaining healthy growth. The usual remedy for their expulsion is lime or soot water, applied at or a few degrees higher than the temperature of the soil. The former cannot be made too strong, but the use of the latter requires care and judgment. *W. Coleman.*

KITCHEN GARDEN.

The question of the propriety or usefulness of laying down the stems of Broccoli intended to stand through the winter may still be called an unsettled one, since many practical men and good gardeners object to it. I think myself that the necessity, or otherwise, should be taken with a little grain of consideration. I never trouble to disturb any dwarf-growing and hardy sorts, such as Cattell's Eclipse, Carter's Matchless, Dalmeny May, and such-like, but I do think it is a good thing to bend down all the lanky-stemmed taller growing sorts, and cover them with earth up to the base of the leaves. The great point of injury will generally be found at that where the leaves radiate from the stem, and this is most frequently caused by sudden alternations of temperature, from frost to thaw, to which they are subjected in fickle winters, and to which the tall varieties are so much more susceptible than the dwarf sorts, since the foliage of the latter keeps the stems shaded, and they thaw more gradually. In any case now is the time for the operation to be looked to, at the same time if the garden is infested with the short-tailed mouse means should be taken for their destruction, for they are great vegetarians, and find a very comfortable home for the winter under a good head of Broccoli foliage, and a capital lair in the centre of the plant, of which they appear very fond. The fine open weather we have had lately has been very favourable for the autumn growth of the Brassica tribe; plants to stand the winter have grown freely, and are looking healthy and vigorous. See that they are kept free of all decaying foliage, and if necessary the ground stirred up between the rows. The autumn Broccolis of various sorts have come in very freely, and amongst them Veitch's Autumn Cauliflower quite maintains its supremacy as one of the very best, and it is very accommodating as to size, as it may be cut when 4 inches over, and in very good ground may be grown to 10 inches or a foot in diameter. It, however, does not protect itself with foliage, and when grown to the required size should be stored under cover secure from frosts. The sorts which protect themselves may be kept out much longer by bending a few leaves over the centre.

Cabbages to stand through the winter season may now have a final earthing-up, and the stirring of the soil amongst the beds of Lettuces, &c., must be persevered in as long as possible, as it tends greatly to keep in check the ravages of snails, and this operation should be supplemented by dressings of soot and lime mixed together in a dry state. This must be carefully attended to in the case of Cauliflowers under hand-glasses which, owing to the favourable weather, are looking more than usually strong and vigorous and with care will soon be out of the way of the attacks of snails. The same dressing should also be followed up on the beds of Tripoli Onions and the Carrot beds to stand through the winter; in this case the dressing should be liberal and stirred in deeply to disturb grubs. Mazagan and Early Long-pod Beans may be at once got in on well cultivated stiff ground. Before sowing the Beans stir them up in paraffin oil—about a table-spoonful to a quart; no need to soak them any length of time, merely wetting them with paraffin at the time of sowing is all that is necessary. On or about the 20th will be the best time to get in a sowing of Peas on a warm sheltered border, one having a southerly aspect is the best. Daniel O'Rourke and William the First are good sorts for this sowing; the seed of this should likewise be wetted with paraffin before sowing. They are best sown rather shallow, and the earth drawn over so as to form a ridge. Take advantage of the dry weather to finish off the earthing-up of Celery where necessary; stir the soil about the roots of the latest planted crops to stand through the winter, but it is not advisable to earth it up at present, as it stands the frost better when the crowns are fully exposed; the rows of Celery may also have the soil stirred about them, and a few inches drawn up to the plants will help the swelling out and blanching of the large roots, which is their chief excellence. If Globe Artichokes are not already protected let it be done at once; half-decayed leaves are an excellent material for the purpose, and in very severe weather it is also a good plan to introduce a good covering of the same amongst the stems of the dwarf winter Broccoli. *John Cox, Reddick.*

THE Gardeners' Chronicle.

SATURDAY, NOVEMBER 10, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Nov. 12	Sale of Dutch Bulbs, at Stevens' Rooms. Blackheath Horticultural Society's Show. Sale of Stock at the Hovell Birch Nursery, Horsell, by Protheroe & Morris (three days).
TUESDAY, Nov. 13	Sale of Ferns, Orchids, Lapagerias, Lilies, &c., at Stevens' Rooms. Brixton and Clapham Horticultural Society's Chrysanthemum Show (two days). Gravesend and North Kent Chrysanthemum Society's Show (two days). Wimbledon and District Horticultural Society's Autumn Show (two days). Carter's Root and Vegetable Show, at the Agricultural Hall (two days).
WEDNESDAY, Nov. 14	Meeting of the Linman Society, at 8 P.M. Sale of Orchids, at Stevens' Rooms. Southampton Horticultural Society's Chrysanthemum Show.
THURSDAY, Nov. 15	Sale of Nursery Stock at the Whitechurch Rectory, Edgware, by Protheroe & Morris. Ealing District Chrysanthemum Society's Show.
FRIDAY, Nov. 16	Sale of Roses, Fruit Trees, Bulbs, Shrubs, &c., at Stevens' Rooms.
SATURDAY, Nov. 17	

THE summer has ended, and with it the long series of exhibitions of horticultural societies which are now thickly held in almost every district of the country. In large cities and towns, in smiling looking villages, in near and in remote districts alike, tents have been pitched, and public halls and school-rooms utilised for the purpose of presenting in public the horticultural productions of the neighbourhoods. An immense amount of activity has been put forth, all the agencies that flower shows call into play have been hard at work; competitions have taken place; victors have triumphed and the vanquished mourned; committees have estimated the results, financial and otherwise, some to their gain and others to their loss; and now the curtain has dropped on the varying scenes, and the actors are resting from their labours till the opening year again summons them to renewed exertions. The question may therefore be put—What is the result, on the position and progress of horticulture, of these exhibitions—is it beneficial or otherwise?

On the whole, no doubt, the influence is a beneficial one, but there are shadows cast athwart the retrospect. It cannot be denied that many exhibitions are simply financial speculations on the part of their promoters. A few persons see in a flower show a prospect of profit, they care little for horticulture as such, but they are willing to make it a means to an end; a committee is formed, a schedule framed—very often in the interest of some few plant cultivators whose productions are indispensable to an attractive exhibition. If the day be fine, and the gate money satisfactory, all goes well as a marriage feast, just claims are satisfied; but if a wet day results a collapse of the speculation follows, exhibitors are offered half the value of their prizes, and occasionally litigation is resorted to before a mutual understanding is reached. All such shows accomplish little or nothing creditable to horticulture.

The best and most satisfactory results are attained when a society exists in any locality for the purpose of holding one horticultural exhibition or more during the summer, though societies, as a general rule, fail to use their opportunities to the best advantage. A horticultural society should include all who are personally interested in horticultural pursuits; and, in addition, those who, not having the love of or leisure for gardening pursuits, yet recognise their social and commercial importance, and support movements having for their object the extension and the improvement of gardening in the localities in which they are active. A society supported by the personal interest and annual subscriptions of its members should not degenerate into a mere commercial or financial speculation, though this sometimes happens; the funds necessary to carry on the operations

of the society should be sufficient, if not to actually cover, yet considerably diminish any financial risks accruing from a wet day—a contingency that may be looked for as likely to occur once in three or four years, if not oftener. The financial undertakings of a society should not be greatly in excess of its income derived from annual subscriptions; there must be of necessity a certain amount of speculative forecast, but it should be carefully computed, for debts are soon contracted, and they hang like a millstone round the neck of a committee of management. A horticultural society taking upon itself financial obligations of a serious character, should aim at the establishment of a reserve fund to fall back upon in case of failure from inclemency of weather or otherwise. A society newly instituted should be supported for the first two or three years by means of a guarantee fund, until it is able to establish a reserve fund. Many societies have suffered utter collapse through want of this necessary adjunct; a wet time has followed two and three years in succession. Committees have to make up the deficiency, and tiring of this, resolve on the dissolution of the society. Numerous exhibitions have come to an end in this fashion.

The framing of extravagant schedules is a common failing. The sanguine men in a committee most frequently outvote the cautious members; they want some few features heavily subsidised to draw in outsiders for the purpose of making a show. Money is often little better than fooled away after this fashion, and the local cultivators, taking umbrage at what they deem a slight, foment discord, and societies with divided councils are rarely successful. A society should take a high view of its duties. It should aim at doing the greatest amount of good. Primarily it should endeavour to draw out the best horticultural productions of its immediate district; it should also give encouragement to new features of a desirable character—for variety goes a long way towards securing continued interest; and when it has done this—keeping its money prizes within its means, if it has sought to spare, it may then go outside its circle of operations, if it be deemed expedient to do so. But caution is urgently needed in all ventures of this character.

Keen business capacity is a great want on committees of horticultural societies, and this is one reason why nurserymen are sometimes desirable as office-holders on flower show committees; but if nurserymen are admitted at all, it should be with the consent of their fellows in the trade, else jealousies arise and imputations of making an unfair use of opportunities. Be this as it may, the selection of good men of business is a much more important matter than appears on the face of it, and for want of proper caution we have known funds frittered away wildly and uselessly. While, then, practical horticulturists, amateur and professional alike, may reasonably take upon themselves a good share in the management of a horticultural society, let them seek to secure the services of men of position and business capacity in the direction of affairs. Their presence and co-operation may avert disaster, and they will be certain to inspire confidence, as the public are rarely slow to support movements they are enabled to contemplate with approval. As soon as possible after the show is held all claims should be satisfied, the accounts audited, and a statement placed before subscribers and others. If the annual exhibition be held in July, a general meeting of the supporters of the society should be convened in December and January, in order that the executive may take counsel with their constituents. It greatly assists in the direction of keeping alive an interest in the society.

At the general meeting the committee of direction should be elected for the ensuing year, and power be then given to revise the schedule of prizes and issue it, and fix the day of exhibition without delay. This gives intending exhibitors ample time to prepare their exhibits, and commensurate space in which to prepare all necessary details. Hurried work is rarely so thorough or so satisfactory as that

accomplished by time and with due deliberation of purpose.

— We have several times had occasion to speak in the highest terms of the BEDDING AT CLEVELAND HOUSE, Clapham Park, as standing in the very foremost rank of summer decorative displays, more particularly in reference to the style now well known as carpet-bedding. We now give an illustration (fig. 117) of a Vine border so arranged. The materials used were such as are generally employed in this kind of bedding, but the arrangement was so far different that the ground for some parts of the design was suok some inches below the ordinary level, whilst for the accommodation of such plants of taller stature used to stand up in relief small beds were raised, which further assisted in breaking the too formal and objectionably even surface usually seen in this description of gardening. The plants in this way elevated were small examples of *Dracæna australis*, *Chamaepeuce diacantha*, and *Echeveria metallica*. The sunk portions were filled with *Nertera depressa*, *Sedum glaucum*, and *Golden Pyrethrum*, and the rest of the filling consisted of *Echeveria secunda glauca*, *Sempervivum californicum*, *S. tabulaforme*, *Sedum lydium*, *Mesembryanthemum cordifolium variegatum*. The subjects used to give colour were *Alternanthera amœna*, *A. paronychioides*, *A. versicolor*, *Coleus Verschaffeltii*, and *Pelargoniums Crystal Palace Gem* and *Mrs. Kingsbury*, up to the wall of theinery. The arrangement collectively was one of the very best and most effective which Mr. LEGG has produced, and this is saying not a little. Speaking of Vine borders, we are no advocates for cropping these at all where it can be dispensed with, but it often happens that vineries are placed in such positions that it becomes an absolute necessity, for appearance sake, to plant the borders with something, as in the present case; and the effect upon the Vines is greatly different according as different plants are used. Here, as will be seen, there were no gross feeders greedily sucking out the nutriment requisite for the sustenance of the Vines, and the continual application of water in dry weather to many of the plants employed, insured the border being kept sufficiently moist, so that the Vines were not likely to suffer through want of moisture. That they were quite at home under the treatment was evident from the fine crops which they have this, as well as preceding years, produced, and which were in keeping with the rest of the gardening here, whether as relating to the flower gardening, plants grown in pots—large specimens of subjects the most difficult to cultivate, as well as small things for general decoration; or the indispensable occupants of the kitchen garden, which collectively have always been in such condition as to evince Mr. LEGG's undoubted abilities as a general gardener. It is to be regretted that, as Mr. LEGG resigned his charge of the gardens at Cleveland House last week, we may not again have the pleasure of including his *recherche* displays amongst the horticultural attractions of the metropolis, but we hope soon to hear that he has met with an appointment worthy of his great ability.

— Mr. MACDOUGALL, gardener, Carbury Tower, Musselburgh, was presented on Friday afternoon, October 26, by his friends and well-wishers, on the occasion of his leaving his present situation, with a piece of silver plate, a beautiful timepiece, and a purse of sovereigns, as a mark of esteem and friendship shown towards him by his personal friends in Carbury and its neighbourhood.

— The HEAVIEST BUNCH OF BLACK GRAPES that has ever been grown, or, we should say, that has ever been recorded, is now on view at Mr. NOBLE'S, Florist and Fruiterer, 22, South Frederick Street, Dublin. The variety is *Gros Guillaume*, and the grower, Mr. ROBERTS, gr. to the Countess of CHARLEVILLE, Charleville Forest, Tullamore, King's Co. Its weight is 23 lb. 5 oz.; length, 24 inches; and width across the shoulders, 22½ inches; and in point of colour, bloom, size of berries, and general finish, it is described as all that could be desired. It came off the same Vine that produced the large bunches which Mr. ROBERTS exhibited twelve months ago at the Royal Horticultural Society of Ireland's Exhibition held in Dublin. It will be remembered that three of these bunches weighed collectively 45 lb. 6 oz., and the heaviest of the trio turned the scale at 16 lb. 6 oz. A portrait of this bunch was given in our number for January 27 last. Up to this time the largest bunch of black Grapes that we have any record of was Mr.

HUNTER of Lambton's famous Black Hamburg, which weighed 21 lb. 12 oz., and, singularly enough, this bunch also made its first public appearance in Ireland, being shown at the International Fruit Show held at Belfast in August, 1874. Mr. HUNTER then beat the largest bunch of black Grapes on record, which was one of the same variety—Black Hamburg—weighing 13 lb. 2 oz., and shown by himself the previous year at Manchester. Mr. ROBERTS' monster bunch now stands third on the list of heaviest bunches (irrespective of colour), being 2 lb. 15 oz. less in weight than the bunch of Raisin de Calabre, 26 lb. 4 oz., shown by Mr. CURROR at Edinburgh in September, 1875, and 2 lb. 5 oz. less than the White Nice, 25 lb. 15 oz., shown by Mr. DICKSON, of Arkleton, at the same time and place.

Our indefatigable friend, Mr. WORTHINGTON SMITH, not content with exploring the mysteries of

tunity, and they may forward their subscriptions to the Treasurer, Mr. SHIRLEY HIBBERD, Bridge House, Stoke Newington, N.

Branches of the remarkable South American shrub COLLETTIA CRUCIATA, Hook., were forwarded by the Rev. T. H. SOTHEBY, of Laogford Budville, Somerset, for exhibition at the last meeting of the Linnean Society. These, it seems, were derived from the primarily introduced stock in Lady ROLLE's garden at Bicton. They were of unusual vigour.

OSMANTHUS FRAGRANS is flowering in the cool Economic-house at Kew, and filling the division with delicious perfume. The flowers are used in China for scenting Tea, and the green kind known as Pekoe is much prized for the fragrance imparted. Another specimen is flourishing on the wall outside, but it is most appreciated when grown under glass,

a show house. A large permanent iron framework is also to be put up over the Exhibition ground. We also learn that the exhibition announced to take place on the 27th inst. at the Town Hall, will be held in the gardens on the above date.

The vitality of popular errors is a feature as marked as it is unpleasant. One of these errors, as we believe, is the statement that the EUCALYPTUS has any special power of averting or destroying malaria, apart from its rapid growth and transpiration, and the improvements in the condition of the soil consequent on planting. As an illustration of our remark, we refer to a statement by a correspondent of *Nature* that he and many others known to him had suffered from malaria in the very heart of a Eucalyptus forest. But if the anti-malarial qualities of Eucalyptus are open to doubt, what shall we say as to the ridiculous statement that

FIG. 117.—CARPET BEDDING ON A VINE BORDER AT CLEVELAND HOUSE.

the Potato disease, has turned his attention also to the devising a process of photographing direct on the wood, so that the engraver may follow Nature's own lights and shadows. The processes hitherto employed have all been more or less unsatisfactory, but if we may judge from the samples of "CRYPTOTYPE," as Mr. SMITH calls it, which have been submitted to us, success seems within Mr. SMITH'S reach. A Cryptotype of the Rev. M. J. BERKELEY on wood, enlarged from an ordinary *carte de visite*, is certainly an extraordinary reproduction.

The DALE TESTIMONIAL has not thus far obtained such attention from growers of the Chrysanthemum as we think it is entitled to; but as the enthusiasts in the autumnal flower are now everywhere gathering in force, perhaps advantage will be taken of the circumstance to promote a good cause. We are advised that the subscription list will shortly be closed, therefore those who contemplate subscribing will do well to embrace the present golden oppor-

and in pots it flowers profusely. It is grafted on Privet at Kew, and apparently with much advantage. *Cinchona officinalis* and *Crotalaria juncea* (Sunn Hemp) we may mention as flowering in the warm end. The flowers of the latter are extremely beautiful, resembling in a great degree the common yellow Broom.

The first ordinary general meeting of the session of the INSTITUTION OF SURVEYORS will be held on Monday, November 12, at 12, Great George Street, Westminster, S.W., when the President, Mr. EDMUND JAMES SMITH, will open the session with an address. The chair to be taken at 8 o'clock.

At the recent sale at Manley Hall, the Council of the ROYAL BOTANICAL AND HORTICULTURAL SOCIETY OF MANCHESTER purchased the large Azalea-house, which will shortly be erected in the Society's gardens at Old Trafford, and be used as

the Eucalyptus trees are somehow inimical to most quitoes? Nowhere, we believe, are these pests more troublesome than in the Eucalyptus forests of Australia. It is a pity that such false and exaggerated statements should be made, as they are sure, in the end, to excite a prejudice against a tree whose utility is likely to be very great.

The following are the proposed changes in the present system of REGISTERING LETTERS AND ISSUING POST-OFFICE ORDERS. From January 1 it is intended to reduce the registration fee from 4*d.* to 2*d.*, and to indemnify the owner, provided of course all regulations have been complied with, to an extent not exceeding 40*s.*, in case of the letter or contents being lost during transmission by post. It is hoped that this will save postmen the temptations to theft, too often offered at present by the despatch of unregistered letters containing articles of value. From the same date the commission on money orders for less than 10*s.* will be raised from 1*d.* to 2*d.*, the present rate

being attended with a very heavy loss to the Exchequer. For the convenience of persons residing in the rural districts, the walking postmen who collect letters will, for the first time, receive letters for registration and give a receipt.

— The following Orchids are now in flower in the collection of Dr. PATTERSON, Fernfield, Bridge of Allan, N.B. :—

Cypripedium barbatum, two flowers on one stem	Dendrobium chrysanthum
.. niveum	.. vestita rubro oculata
.. insigne	Lycaste lanipes
Vanda cœrulea, eleven flowers on one stem	.. Skinneri, two large flowers on stem
.. tricolor, Veitch's var., two spikes	Laelia Perrinii
.. tricolor Patersoni	.. anceps
Limatodes rosea	.. superbians
Pleione lagenaria	Odontoglossum Rossii majus, fine var.
.. Wallichiana, two vars.	.. bictoniense
.. prœcox	.. Uro-Skinneri
.. maculata	.. constrictum
Mesospidium sanguineum	Calogyne speciosa
Miltonia Moreliana aurubens, Wingate's fine var.	Masdevallia Veitchiana
.. candida	.. ignea
.. spectabilis, rare var.	Zygopetalum Mackayi
.. Glowiesii major	Cattasetum species from Bahia
Oncidium orthorynchum	Phalaenopsis grandiflora
.. verrucosum	Neottia picta maculata
.. Rogersii	Epidendrum rhizophorum, in flower all the year round
Cattleya Loddigesii, two vars.	Sophranites cœnea
.. Leopoldii	

— The ordinary monthly meeting of the SCOTISH HORTICULTURAL ASSOCIATION was held in 5, St. Andrew's Square, on Tuesday night, under the presidency of Mr. MALCOLM DUNN, Dalkeith Gardens. Fifteen new members were elected; and a very interesting paper on the hybridisation of plants was read by Mr. ROBERTSON BROWN, Abercorn. A letter was also read from Mr. DOWNIE, of Messrs. DOWNIE & LAIRD, offering a prize of £5 to journey-men gardeners for the best original plan of a flower garden. Votes of thanks were voted to Mr. BROWN and Mr. DOWNIE, and the offer of the latter was remitted to the Council to make the necessary arrangements for a competition.

— Mr. GEORGE TEMPLE, late gardener at The Cliff, near Brighton, has been appointed gardener to Lady GEORGIANA CODRINGTON, Dodington Park, Gloucestershire.

— Under the name of "SANGUINNAIRE, OU THÉ ARABE," a packet of the flowers of *Paronychia argentea*, Lam, has recently been received at the Kew Museum from Consul General PLAYFAIR, of Algiers. This Tea, which is new to us, seems to be sold not only in Algeria but also at the Parisian pharmacies. It is sold essentially as a medicinal agent for alleviating chest complaints or assisting weak digestion, and a teaspoonful of the dried flowers is stated to be sufficient to make a breakfast-cupful of the infusion. We are unable to give any opinion as to its efficacy in a medicinal point of view, we can only say that apparently it is of a very weak nature, and has more in common with a weak solution of hay than anything else we can liken it to. The name of the plant furnishing this tea is not stated on the packets, its determination was made after comparison at Kew.

— An example of an undetermined species of FUNGUS IN SUGAR CANE was exhibited at the Linnean Society (November 1), by Mr. E. M. HOLMES, who stated that it had been forwarded to him for examination, with a memorandum that this same growth had been the means of causing the destruction of a plantation in the South, in India.

— A remarkable instance of SLOW GROWTH and durability of a CONIFEROUS TREE is recorded in the ninth volume of the *Transactions and Proceedings of the New Zealand Institute*, by Mr. JOHN BUCHANAN. The tree in question is *Podocarpus spicata*, the Matai of the Maoris, a common forest tree almost throughout the island of New Zealand. Mr. BUCHANAN describes a prostrate trunk, which was pointed out to him in a valley near Dunedin. He calculates that the tree must have lain where he saw it at least 300 years from the fact that its trunk was enfolded by the roots of three large trees, which must have grown from seed since its fall. The three trees seated upon it and rooting in the earth on both sides, thus holding it in their embrace, are all *Griselinia littoralis*, with trunks 3 feet 6 inches in diameter. They were recently felled, and the growth rings count over 300, thus approximating 300 years, during which

the timber of the *Podocarpus* has remained so fresh and sound that it has since been split into posts for fencing purposes. The measurement of the fallen trunk was 135 feet long, and 3 feet in diameter at its base; and as the sap-wood and branches were gone it must have measured, when alive, at least 160 feet in height, with a diameter of 4 feet. Mr. BUCHANAN states that the wood is close-grained and heavy, and of a dark reddish-brown colour, and the yearly growths very narrow and numerous, showing eighty-eight rings to an inch! The semi-diameter being 18 inches gives for heart-wood alone a period of 1536 years, and with sap-wood growths added Mr. BUCHANAN calculates that the age of the tree when it fell was at least 1880 years. If to this again be added the 300 years during which it has lain prostrate, we have a period of 2180 years, within which no great disturbance of the forest has taken place in the immediate neighbourhood of Dunedin. There is no doubt of the great age of this tree, but we think Mr. BUCHANAN must have based his estimate upon an inch of the outer part of the heart-wood, which would be very misleading; and we also think that the period of 300 years he assigns to the sap-wood which had disappeared too high. Again it is possible that trees make two growths annually in the climate of New Zealand.

— We hope shortly to present our readers with a full account, accompanied by illustrations, of the new arrangements for HEATING the PALM HOUSE at KEW, as devised by Mr. RIVERS, C.E., the engineer to the Board of Works.

— A kind of Coffee that would flourish in a temperate climate would doubtless be a great boon to the inhabitants of some of our colonies, New Zealand for instance. That such a plant probably exists we learn from a paper read by Mr. J. C. CRAWFORD before the Wellington (New Zealand) Philosophical Society, in February of the present year. It is no other than *Coprosma Baueriana*, a shrub now not uncommon in English gardens. Another species, *C. lucida*, has also the reputation of yielding berries, which are even in an uncultivated state a very good substitute for Coffee. But Mr. CRAWFORD particularly calls attention to the claims of *C. Baueriana* for a thorough trial to test the value of its seeds as the basis of a wholesome and agreeable beverage. It is a small tree or shrub, very hardy, and flourishes well close to the sea and in most exposed situations. It bears fruit in abundance, apparently without fail; and it is easily propagated from cuttings and seeds. Horses and other animals greedily devour the foliage. Mr. CRAWFORD collected a quantity of the berries, the seeds of which when roasted and ground have a splendid coffee aroma, and when made into coffee the result seems to be thoroughly satisfactory. And he is of opinion that they have a great source of wealth in this plant.

— Mr. E. B. JONES, late gardener at Calvey Hall, Tarporley, has succeeded Mr. W. M. HARRISON as gardener to Sir RICHARD BROOKE, Bart., Norton Priory, Runcorn, Cheshire.

— In the *Revue des Sciences Naturelles* we find some remarks by M. BARTHELEMY which are of interest in relation to the question of the DESCENT OF THE SAP which has excited some attention of late in our columns. The well-known effect of a ligature or of ringing in producing a swelling above the ring or ligature, as illustrated in our columns p. 309 has been explained by some writers on the assumption that gravity was the cause of the swelling. In answer to this objection M. BARTHELEMY experimented on the pendulous branches of certain trees, Weeping Willow, Ash, &c. In these cases the effect of a ligature or of ringing was seen in the production of a swelling below the ligature, just as in the case of the erect branches, but in this case of course in opposition to the direction in which gravity would act. M. BARTHELEMY varied his experiments in different manners, but always with the same substantial result.

— The culture of MIGNONETTE in pots for the London market is an interesting aspect of horticultural enterprise. Those who are accustomed to see the charming pots of Mignonette in Covent Garden market, so compact in habit and yet so robust in growth, have generally but little acquaintance with the mode of culture adopted by the growers. One of the largest of these is Mr. JOHN REEVES, of Acton, and on his nursery may now be seen something like

15,000 pots of Mignonette in various stages of growth, from pots nearly ready to send to market, to those where the seed is now coming through the soil. The strain grown is a remarkably good one that has been well selected, and comes near to what is known as Parson's Giant Mignonette. The seed is sown thinly in 48-pots, in a good light potting soil, and then thinned out to about eight plants as soon as large enough. At the height of about 6 inches these plants throw up blooming spikes, with side flowering branches coming up also. The seed sowing period commences in July, and it is sown successively up to the middle of October. The earliest sown seed has by this time grown into plants that are blooming ready for market. When the seed is sown the pots are stood in somewhat slanting shallow cold pits, so that the pots come nearly to the glass. It is well sprinkled and shaded from the sun, and growth soon takes place. After the plants are thinned out, they are kept fully exposed to light and air, the lights being put on only when absolutely required. A pot of sweetly fragrant Mignonette in autumn is a pleasant surprise; and this method of growing this popular flower ensures with that grown in the open ground a supply all the year round.

— We learn from Mr STEVENS that Mr. EDWARD KNOWLDING, from the gardens of the Duke of SUTHERLAND at Trentham, has received the appointment of head gardener to the Duke of LEINSTER, at Carton Park, near Maynooth. Mr. KNOWLDING has given the greatest satisfaction while employed at Trentham; and it may therefore be expected, now that a wider field is open to him, that the ability he has displayed in a subordinate position will prove the passport to success in the more responsible post he will now occupy.

— The VEITCH MEMORIAL PRIZES will again be offered in 1878. In accordance with the powers entrusted to them the trustees have allowed part of the interest to accumulate, with the intention of raising the fund by those gradual accretions to £1000. It has now been decided to set aside for 1878 £50 as money prizes, to be offered at the show of various selected provincial horticultural societies widely dispersed over the United Kingdom. Each prize will consist of the handsome but inexpensive Veitch Memorial Medal and £5. The societies to which it will be offered for 1878, and the subjects provisionally fixed on, but subject to revision to suit the dates of the respective shows, are as follows:—

- MANCHESTER.—The best specimen Orchid.
- YORK.—Three bunches of Black Hamburgh Grapes.
- CLAY CROSS.—One dish of Peaches and one of Nectarines.
- HEKEFORD.—Twelve cut blooms of the best new Rose sent out within the last five years.
- DEVON AND EXETER.—A collection of twelve kinds of vegetables, distinct.
- BRIGHTON.—One bridal and one ball-room bouquet.
- WOODBIDGE.—Three stove and greenhouse plants, distinct.
- READING.—Three stove and greenhouse plants, distinct.
- DUBLIN.—Three bunches of Muscat of Alexandria Grapes.
- BELFAST.—Twelve cut blooms of the best new Rose sent out within the last five years.

All the exhibits are to be shown by *bonâ fide* gardeners alone, and to display superior cultivation. We think the distributive method of offering these prizes an excellent one, since it will stimulate horticultural effort in various directions and in widely separated centres.

— Dr. GEORGE KING, Superintendent of the Royal Botanic Gardens, Calcutta, has now, it seems, settled the question as to the identity of the plant bearing the so-called WINGED CARDAMOM of the bazaars of Northern India. This moot point the late Mr. HANBURY was much interested in. By Dr. PEREIRA it was supposed to be the produce of *Amomum maximum*, Roxb., but this is indigenous to Java. To the Indian species ROXBURGH gave the names *A. aromaticum* and *A. subulatum*, and this latter Dr. KING proves (in his recent communication to the Linnean Society, November 1) is that which yields the Winged Cardamom of Nepal. Its true habitat is the Morung Mountains, and not the Khasia Hills, as VOIGT averred.

Home Correspondence.

The Late Potato Show at the Aquarium.—Your correspondent, "A. B.," supposes I have entered into discussion with him. I have not. I directed your attention to matters of fact in connection with this subject because you signified your approval of his letter. To expostulate with you, for whom I entertain respect, is one thing, and to discuss with him (or her, or it) is another. He has accused me and my friends of dragging a society through the dirt to promote the sale of gin and our own glorification. And after this he has the audacity to speak of "my friend Mr. Shirley Hibberd." I am no friend but an enemy to the anonymous slanderer, and I shall esteem it a favour if in any further communications from that source you will, if my name should appear, carefully erase it. I have laboured hard to keep my name sweet, and intend, even if at some cost, that it shall not be dragged through such mire as "A. B." appears to have prepared for it. And once more as to matters of fact, addressing myself to you only, that you may be induced to reconsider your approval of a principle undefined. The very improper letter of "A Committeeman" gave rise to this useless correspondence. The man who wrote that letter was one of the most clamorous for holding the show at the Aquarium, and, having carried his point, was bound to be loyal to the cause, and keep his snail grievance to himself. It is well known that I laboured hard to locate the show at South Kensington; and the end of it was, that I was left in a minority of one. I make no complaint against the manager of the Aquarium; loyalty to the cause would keep me silent unless I had a greater grievance to complain of than the "Committeeman," with his whining abuse of people who complied with his wish and treated him generously; but though I sought to locate the show at South Kensington, I will not again labour to that end at the dictation of an anonymous slanderer, even if fifty editors back him up and approve of his "principle." *Shirley Hibberd, Stoke Newington.* [When the personal element, which has unfortunately crept into this discussion, has been eliminated, there will be an opportunity for discussing general principles on their merits. At present it will be better to close the correspondence. EDs.]

"A. B." and the Royal Horticultural Society. In "A. B.'s" very good letter, p. 564, there is one sentence to which I venture to take exception. A. B. writes as if the "being's end and aim" of the Society was shows; perhaps he remembers, as I do, the fitful glories of the old days at Chiswick, when the Society was fashionable and magnificent; but, poor and persecuted by weather as it has so often been since, surely it is better, when the ground has shifted from under us, to look about for props on more solid and firmer ground. Instead of looking back to the time when the Society had almost the monopoly of shows, would it not be well to look at the present great fact, that there are now twenty horticulturists fond of their gardens and able and willing to back up a national horticultural society if permitted to do so with a moderate subscription, for one who existed in Chiswick show days? Look at the list of subscribers to the National Rifle Association, how many of them go to its great exhibition days at Wimbledon in July? People subscribe because they think it does good useful national work, and they would subscribe to ours for the same reason if they felt the same conviction. I hold that, good and pleasant as shows are, it is not to them that the Royal Horticultural Society should look as its main means of support. *George F. Wilson.*

The Royal Horticultural Society and its Awards.—A friend of mine told me some days ago that the Royal Horticultural Society had sent him 10s. in lieu of two large bronze Banksian medals that had been awarded to him as 1st prizes at the last great summer show. He considered that he had been shabbily treated; I thought he was a lucky man to get the money instead of the medals, seeing that the actual value of the bronze medal is only equivalent to its weight in the Queen's pennies, and sixty pennies weigh nearly 20 ounces, which the Royal Horticultural Society's bronze Banksian medal probably does not. I heard from another friend who showed a good collection of fruit at the same show that the magnificent sum of 10s. 6d. had been sent to him as the value of the 1st prize that was awarded; and I am reminded of this circumstance by a statement made to me the other day by Mr. Deaning, gr. to Lord Lonsborough, that a Lindley Medal which had been awarded to him proved, on being broken, to be composed of white metal gut over, and to be only of the actual value of 4s. 6d. per ounce, which was about the weight

of the medal in question. The Lindley Medal has always been considered in the light of a Blue Riband amongst growers, and has only been awarded to exceptionally fine productions, on account of its supposed value. As a matter of fact, I believe that in gold the medal costs about £13, but I hear that only two of those which have been awarded have cost this amount. Comment on this system of liquidating the Society's debts needs no comment, but should be made public. X.

The National Rose Society.—In your paper of last Saturday it is stated that the subscriptions and donations to the National Rose Society amounted to £67. Will you allow me to correct the error, as they amount to nearly £300. *H. H. D'Ombraim.* [The error would not have occurred had a copy of the balance-sheet been sent to us. EDs.]

The Entire-leaved Tulip Tree.—I would take it as a favour, and I think it would interest others as well, if some one would give information as to the *Liriodendron tulipifera integrifolia*, or entire-leaved Tulip tree. I have been anxious to know whether it really exists in European collections. In the *Arboretum Segrezianum*, just published, it is enumerated, and *Illust. Hort.*, xv., tab. 574, given as reference to an illustration, but there is no figure of it there or anywhere in the work. The entire-leaved form was, I believe, first found wild by Bartram, and seeds are said to have been sent to Europe from the tree, but no one since his time has seen it here, and it has been the fashion for collectors to search for trees less lobed than others, in order to fill orders for the entire-leaved form. In a communication which I had the honour to make some time since to the Philadelphia Academy of Natural Sciences, I pointed out that trees, and most plants in fact, had separate juvenile and adult characters, and that when the juvenescent character was carried through life, as it is occasionally, the plants were the analogues of imbeciles in the animal world; and further, as reproduction is a function of maturity, trees retaining their juvenescent character through life, rarely produced seeds. Those who may like to pursue this subject further will find many curious facts bearing on it in my paper above referred to. I will only say here that this entire-leaved Tulip tree is one of these "imbeciles." The normal condition is always to have entire leaves in its first year's state, and this has simply carried its infantile form with it through life. For other reasons given in that paper, but not necessary to be re-produced here, I may say the lobing or integrity of leaves is often a sexual character, and which therefore will not have any hereditary influence; and I am, therefore, inclined to believe that to preserve the entire-leaved Tulip tree in its purity, grafting or some asexual form of propagation has to be resorted to. In short, I doubt whether much seed was ever obtained from a perfectly entire-leaved form, or, if any seedlings were raised, they would be entirely true to the original. Can any one inform me? I enclose a leaf; you will see there is no sign of a lobe in it. It is from a tree I re-discovered last year. *Thomas Meehan, Germantown, Philadelphia, U.S.*

Do Roots Digest?—In your issue for October 6, p. 441, I see you draw attention to Dr. Carpenter's views on the assimilation of sewage and other decaying organic matter by plants. The question there raised is whether plants, by their roots, absorb and digest decaying organic matter or not? The subject will doubtless receive the attention of vegetable physiologists with time and opportunity, and by-and-by we shall have the evidence obtained by both sides before us, from which we shall be able to arrive at a satisfactory conclusion as to whether plants generally have the power of absorbing and then digesting decaying organic matter. I have an idea that roots have a certain power of digesting and then absorbing decaying organic matter. I have often observed that the fibre of peat and sphagnum decays much more quickly (when used in Orchid growing) when the roots have taken full possession of the contents of the pot compared with what takes place in the case of plants whose roots do not ramify to the same extent as in the other case. I have another case bearing on this point. Two years ago I potted on some Azaleas with very fibry peat, in which there was a good dash of silver-sand naturally. As I had a quantity of the material it was stacked in a shed for future use, and to-day it is still good fibry peat, although not so tough as it was two years ago. But what I want to draw attention to is that a few days since, when regulating the drainage of these Azaleas, I could not find a particle of fibre in those pots which were well filled with roots, not even over the cracks, where I placed the very toughest fibre which I could find, but in those pots not very well filled with roots the fibre was still apparent, although considerably decayed. No doubt the waterings and the higher temperature assisted in the decomposition of the peat in the pots as compared with that in the shed, but how are we to account for the fact of its total disappearance where the roots

were abundant, and its partial disappearance where the roots were less abundant, but with other conditions the same, if we do not account for it by supposing the roots to aid in its disintegration? A. H.

Mandragora microcarpa.—In the *Gardeners' Chronicle* in the early part of the present year (vol. vii., new series, pp. 212 and 438), the flowering of *Mandragora microcarpa* at Wallington, the seat of Sir Walter C. Trevelyan, was recorded. Since then the plant has produced fruit, as has also a plant of *M. officinalis*, and thus an opportunity has been afforded of showing how distinct are the two species. These two plants grew side by side, but *M. microcarpa* began to flower several weeks before *M. officinalis*; indeed, the former continued flowering all through the last severe winter and spring, and quite uninjured, while the leaves of the latter were somewhat injured by the frost. All the parts of *M. microcarpa* are smaller than in *M. officinalis*, and the flowers and leaves are of a dark purplish tint. The fruit is also different, being of an oval form, and smaller than that of *M. officinalis*, which is quite round. Though I have not been able to find a figure of the plant under the name of *M. microcarpa* in any botanical work, yet I am inclined to think what Gerarde* and Bulliard† figure and describe as the "female Mandrake" must be the plant in question. Moreover, it appears to me that the plant will be found to be identical with the plate of *Atropa Mandragora* in Sibthorp's *Flora Græca* (vol. iii., t. 232). Perhaps, also, *M. autumnalis* (figured in Sweet's *British Flower Garden*, 2d series, vol. iv., t. 325, from a plant which flowered in the month of December, many years ago, at Abbotsbury, in Dorsetshire) and *M. microcarpa* may be one and the same species. D. W.

Worm Farming.—I think the person who wrote the paragraph headed "worm farming," at p. 570, could not have had much practical experience in fishing, and certainly not in worm catching. It is there stated that dew or lob, cocksbur and branding worms are caught in the meadows at night. I have myself caught thousands of dew-worms in the manner mentioned, but I never heard of any one catching either brandlings or cocksbur in this way, firstly, because they are never found except in a manure heap, ground recently manured, and similar situations; secondly, as the cocksbur is usually about an inch in length, certainly not more than an inch and a half, any one would be very clever to catch them in the grass at night, even if they were there to be caught. Also I do not see how catching worms, keeping them a week and selling them, can be called worm farming, and especially breeding, as the breeding takes place in the fields without the slightest human interference. Lastly, the object in keeping worms a short time in moss is not to toughen them, as there is very little difference in toughness between a worm just caught and one that has been kept a week. The real aim in keeping them is that they may scour themselves and thus become brighter and redder, in order as it is supposed to make the bait more tempting to the fish. *Charles E. Pearson, Chitwell.*

Culture of Schizanthus.—This is one of the most elegant and showy annuals we have when grown-on as a pot plant. It is not so much grown as it deserves to be. It is of very easy culture; the seed should be sown and but very lightly covered about the middle of August, and put into gentle heat. A piece of glass should be put over the pot, as it will keep the soil moist without too much watering. The seed will soon germinate, and as soon as the plants are sufficiently large to handle they should be pricked out about six in a 4-inch pot, and kept close in a little heat until established; then brought into a more airy part of the house. When the plants begin to fill the pots with roots they should be repotted, one plant into a 4-inch pot. The compost I use is loam and leaf-mould, with a little sand added to keep the soil open. Keep them as before for a short time, not allowing them to be drawn for want of a little attention, and when the plants are about 4 inches high pinch out the centre, which will cause them to make several breaks, and form nice little plants. Let this be done about a week previous to potting-off again, as no plant should be stopped and then potted at once. If properly handled they will require another shift into

* Gerarde in his *Herbal, or General Historie of Plantes* (1633), says, "The female Mandrake is like unto the male, saying that the leaves hereof be of a more swart or darke crooke colour; and the fruit is long like a Pearre, and the other is round like an Apple."

† Bulliard (*Herbier de la France*, 1780): "*Mandragora flore subcæruleo-purpurascens* = *Mandragora femina*.—Cetle espèce diffère essentiellement de la précédente, tant par la forme et la couleur de ses fleurs, que par la forme et le volume de son fruit, la surface et la couleur de ses feuilles." And I may just add the following quotation from the late Dr. Daubeny's *Lectures on Koman Husbandry* (1837):—"Dioscorides mentions a male and female kind of Mandrake, which, Sibthorp says, are merely varieties, the male being larger and more downy than the female; but Pliny distinguishes the male as the white variety, and the female as the black, corresponding with the spring and autumnal *Mandragora* of modern botanists."

48-sized pots about the middle of November, using a little rotten manure in the compost, as they delight in a rich soil. In this pot the plants will stand through the winter months. About the middle of February give them a shift into a size larger pot, using the same compost. Each plant will require a neat stake, to keep it upright. After each shift be careful not to use much water, a slight sprinkling overhead being as much as required until more roots are formed. During winter water only at the roots, giving no more than is absolutely necessary, as they are liable to damp-off. For their final shift put them into 8-inch pots, and keep them staked to your own taste, as they are plants which can be brought into any shape which the cultivator may think fit. They are also well adapted for hanging baskets in the conservatory or greenhouse; in fact they will make pretty objects anywhere. If these few points are attended to they will amply repay the cultivator. A little liquid manure occasionally will prove very beneficial to them just before flowering commences, which will be in April and May. As a cut flower it forms a very prominent feature in stands, also for bouquet work, on account of its durability. The following I have found make a nice variety:—*humilis*, *Grahami*, *Priestii*, *retusus*, *retusus alba*, *occulata grandiflora*, *pinnatus*. *W. Biggs, Sandfield Park.*

Egyptian Vegetable Remains.—In the late Alexander Braun's notes on the "Remains of Plants in the Egyptian Museum at Berlin," a translation of which appeared in last week's *Gardeners' Chronicle*, one of the plants mentioned as being represented by its fruits in both the Vienna and Florence collections, but not at Berlin (the fruits in this latter collection having been wrongly identified as such), is *Cordia Myxa*. It may not be generally known that the wood of this plant is credited with having been used by the Egyptians for making their mummy cases. Amongst some specimens of fruits, seeds, &c., received some time since at the Kew Museum from the tombs at Thebes, were some pieces of wood of mummy cases, and upon comparing these with specimens of the wood of *Cordia Myxa* already contained in the museum, little doubt was left as to their identification. The wood is soft, and at the present time is of little or no use except for fuel, for which purpose it is said to be especially adapted, owing to the readiness with which fire is kindled with it by friction. It is of a yellowish brown colour, with numerous fine white lines forming the medullary rays closely set together. In India at the present time the fruits are eaten when ripe, and are also used for pickling. With regard to the fruits of *Hyphæne Argun*, which, it is stated, are "buried by the natives for a time, whereby the albumen obtains an agreeable flavour, resembling the Cocoa-nut," no mention is made of the edible nature of the fibro-fleshy portion, which encloses the albumen as in the Doom Palm itself, and, like that Palm, has a sweetish gingerbread flavour; indeed, it is said as a proof of its affinity with *Hyphæne* in contradistinction to that of *Areca*, in which genus it was first placed, that the "fibrous layer in the pericarp is wanting." In the Kew Museum are fresh fruits of *H. Argun*, from which it seems that the normal size is about that of a large and plump Olive, the fibro fleshy pericarp being nearly a quarter of an inch thick, whitish, mottled with brown, and the albumen rimmed with brown markings. Considering the thickness of the pericarp in a fruit of this size, and its agreeable sweetish flavour, which is still distinctly marked in the fruits in the Kew collection after being preserved there for several years, it is somewhat remarkable that we have no evidence of its value on this account. That the fruits of the common Doom Palm were used as food by the ancient Egyptians is apparent from the fact that amongst the collection previously referred to as being found in the tombs at Thebes and forwarded to Kew, is a mass forming a kind of cake and composed of the crushed fruits of this Palm. While writing of *Hyphæne* I may perhaps say that I have examined the large collection of fruits of *H. thebaica* in the museum, and in none is there a trace of the development of more than one ovule. On the question whether or not the Olive was cultivated by the Egyptians, the fruit not having been found in any of the graves or coffins, I may say that a small vase containing a thick, dark-coloured oil was amongst the collection before referred to, and upon submitting it to examination and analysis it was stated to be Olive oil. *John R. Jackson, Museum, Kew.*

Peach Failure in 1877.—Those who still adhere to the old practice of growing their Peaches on the open wall must have had their calculations sadly upset this year. During this summer I have seen in more than one county in Ireland the labour of years dashed aside; trees beautifully trained, with every part as neat as the most fastidious could wish, but all to no purpose. We have now to deal with dead trees and dead branches, and I may say trees in consumption. Query—What is the matter? I do not know. Ask the gardener. He does not know either. All he knows is, that he covered the trees with nets, &c. They

bloomed well, and in most cases set their fruit well, but all at once the leaves wither, the branches die off, and the tree that carried such beautiful fruit last season is dead. What is the cause? Was it those bitter east winds that we had, or the continual cloudy, damp weather during February, March, and April? During those three months we had rain on sixty-three days and nights, but no severe frosts (not more than 8°, March 20), but during that time we had very bitter winds from the east, and to that I believe we must attribute not only the loss of the crop but of the trees as well. I believe in most instances in the unheated orchard-houses the crop has been successful. That ought to teach us that glass, however placed, is the best protection. At Woodstock we depend entirely on indoor Peaches. We commenced to gather in the beginning of July, and have not yet finished. We have gathered nearly 1000 fruit, not all from unheated houses, but nearly so. I must also say that Sweetwater and Black Hamburg Grapes ripened perfectly under the roof of a Peach-case (not heated), and this at nearly 600 feet above sea-level, with the ground sloping to the east. I would, therefore, say to all who have walls, cover in at least some portion of your trees, and save the disappointment in future seasons like the one we have just passed through. *G. Dodd, Woodstock Park.*

Dendrobium album.—In the gardens of J. C. Bowering, Esq., Forest Farm, near Windsor, I noticed a few days since a plant of *Dendrobium album* growing and flowering, quite as freely as *D. chrysanthum*, which it much resembles in growth, one hurb I measured being 3 feet 6 inches long, clothed with flowers as white as those of *Odontoglossum pulchellum*, with the exception of a small pale yellow blotch in the interior of the labellum, some of the flowers measuring 2 inches across. It is a plant worthy of a place in all choice collections of Orchids. *S. Johnson, Royal Nurseries, Ascot.*

The Tomato Crop.—Your correspondent's case with regard to Tomatos, p. 565, is similar to my own, and I know it to be a general one in this neighbourhood, and I was rather surprised when I read the remark on which he comments. Here they grew very rapidly, and blossomed well, but owing to the unpropitious weather (with but few exceptions) did not set. At the beginning of September a disease (similar, if not identical with the Potato disease) appeared among them and spread with such rapidity that in a very short time most of them were a mass of decay. A few, however, escaped and continued to blossom, and during the favourable autumn set well, but were all destroyed by frost on the night of October 16. *H. Hill, The Gardens, Glynn Park.*

—We have experienced precisely the same difficulty in the ripening of the Tomato this season as your correspondent, "T. P.," p. 565. Our Tomatos this season occupied the same quarters as they did last year, when we had abundance of ripe fruit, and this season we only gathered about two dozen ripe. On account of frost a few weeks ago we had them all cut from off the plants, and hung up in bunches in one of the vineries, where they are ripening tolerably well. *Solanums* and *Aucubas* have not got one quarter so many berries as in previous years. *R. Greenfield, Priory Gardens, Warwick.*

Tomato and Solanums.—In reply to "T. P.'s" query at p. 565, I beg to say that with us (near Salisbury) the Tomato crop has been very good and satisfactory in every respect. They have been planted and trained against the walls and attended to in the usual way—thinning of the foliage and shoots, training, &c. The same may be said of the *Solanums*, which have been planted out at the proper time (May) in suitable soil, and watered and stopped, lifted and potted in due time, and with consequent results—heavily laden with berries, which are now colouring nicely and to our entire satisfaction. *H. W. W.*

Gardeners and their Employers.—Would you allow me to ask a few questions through the medium of your journal? 1. Supposing that a gardener (head) has been in a situation, say, for two years, more or less, and that when he went to that situation he had taken with him some cuttings, plants, or seeds of valuable exotics, and had grown them, whose property would they be when the gardener left that situation? [We believe the gardener could not legally remove them without permission of the employer, and therefore they become virtually the property of the latter. EDS.] 2. Supposing a gardener to have bought some plants with his own money, without his employer's knowledge, when the gardener leaves has the employer any claim on them? [We should say, Yes. He paid the gardener and found all the conveniences for growing, and, as in the previous case, except the employer permits it the plants could not be removed from the premises without laying those who took them open to a charge of theft, so that on this point also the employer can detain them. Gardeners ought not

to do such things without permission, then such an unpleasant question as this could not arise. EDS.] 3. If a gardener he paid weekly what notice should he have, or should he give, before leaving, supposing there was no arrangement made about that when he was engaged? *H. G.* [Legally only one week's notice is necessary on either side, but the usual rule is to give a month's notice. EDS.]

Autumnal Foliage.—I send you a spray of the newish Purple Birch, which, as you will see, has taken on most beautiful autumn tints, which fact will add much to its other features as a pictorial tree. As a rule, autumn tints this season have been poor and short-lived. *Crataegus azarolus* is, so far as colour goes, as much like *Liquidambar* as can be. Perhaps the most beautiful autumn colour I ever saw is found in the leaves of the rare *Berberis Thunbergii* (a few of which I enclose), which are nearly scarlet. The nearest approach to it was that of the foliage of some starved plants of *Rhus cotinus*, the especial colour of which we seldom see, but perhaps we should if it was planted on dry ledges, in clefts of rocks, and similar positions. Here in the natural soil it keeps green till Christmas. *T. Smith, Newry.*

Vine Mildew was not heard of till found by Mr. Tucker, of Margate, in 1847, but since then the fungus pest has spread abroad, and it is well worthy of inquiry as to the cause of it. Some ascribe it to old or badly ventilated Vine-houses, glazed with dark or green glass; but mildew is often less virulent to such than it is in the best constructed vineries. Formerly Vine-houses were little better than glazed frames placed slanting against a wall, yet Vines would thrive in them free from mildew, while Peaches beside them were seldom free from it, especially the Red Magdalene. This says little for the belief of those who contend that the Vine blight is the same kind as that which affects Peaches; if so, however, that only adds to the vexed question—Why is the Vine fungus so prevalent now and not before? Some suggest that the pest is new, and was introduced on Vines from abroad, as other parasites have been; others that higher culture of the Vine and sudden changes of climate have rendered it a more susceptible prey for mildew spores. The first, if correct, seems the easiest way of settling the question, while the other opinion does not help it a bit, because the Vine had been long cultivated here in the open air, and in some seasons with success, free from mildew, whether they were weak or strong. As regards changes of climate, our seasons seem to have gone much in the way for "better for worse." However, those who adhere to the theory that sudden changes of weather are the cause of mildew, seem imbued with the belief of the season's poet—"A brush from Russian winds brings on the clammy mildew." It is an old custom in Norfolk to call hazy weather "ruke" or a "mildoc." Such, however, only favours blights by affecting plants so as to render them better prey for their spores as they float in the air. From those, though unseen, parasites grow like plants from seed, whose leaves they blight. That, however, may seem only fanciful, but not by those who know the Greek term "cryptogamia," applied by hotanists to plants low in the grade of vegetable life. If this should catch the eye of Mr. Berkeley, who has revealed much on the hidden or mysterious growth of vegetable parasites, perhaps he will have the goodness to notice if the Vine mildew is of foreign origin, as hinted in the foregoing remarks, and thus greatly oblige others as well as *Y. Wighton, Cosey Park.*

Root Pruning.—I think your correspondent (p. 521) makes a mistake if he thinks that root pruning will in any way bring about maturity in the wood of the past season, as I have found it otherwise. I have given much attention and study to it for many years. But my method might more properly be termed "lifting," and although it differs widely from Mr. Rivers' method, I must confess that I am solely indebted to him for it. I think your correspondent is quite right in saying that the larger roots convey most water to the branches. Perhaps few have noticed that there is a corresponding similarity between root and branch, but I have noticed that below the side of the tree where there is a large branch will be found a large root. But to make the matter more plain plant a tree in poor soil and you will have a long weak growth of branches, and if you examine the roots you will find that they too are weak and long, and this when there is everything favourable to the tree's development as far as light, air, &c., are concerned. On the other hand, take for example a tree in a wood under other trees and there we do not wonder about the weak long growth of the branches; but let any one examine the roots of such a tree and I think they will be found long and weak too. Now this is not occasioned by the want of nourishment as it was with the tree in the poor soil, for you have, it may be, several inches of decayed vegetation. Now I must confess I am not a sufficient physiologist to know why this is, all I know is that it

is so. And again, by frequent and judicious root-pruning, lifting, or what you please to term it, so that you can give frequent (if necessary) stimulants, you get a beautiful mass of fibres very near the surface and not far from the stem, which in my opinion is most important, and not only so but all you can desire—above-ground fine short-jointed wood full of flower-buds and the flowers, too, nearly twice the size of those on ordinary trees, flowers that have much more (in my opinion) power to resist adverse weather, &c. I fully agree with your correspondent that pruning should be done early, and also that it should not be too severe—much better to raise the roots; but I do not agree that all roots within a certain radius should not be removed. I used to draw a circle round the tree, guided by its size, &c., and cut off every root, digging a trench with the spade and working the soil into the trench with a fork, so that every root might be discovered, and then turn the tree over, leaving a few roots on one side, so that the check might not prevent a crop of fruit the first year, but the following would be the most abundant; you then have the chance of adding manure or compost at will. I should much like to see this matter gone into, and I can assure your readers it will repay all trouble and expense.

George Lee, F.R.H.S.

—A correspondent signing himself "F." recommends the timely root-pruning of fruit trees, in order to counteract in a measure the evil influences arising from abnormal growth, which may be fairly traced to the exceptional character of the

superior power of fibre over the more simply constructed things as food suppliers. Nor can we see by what mode of reasoning the fibre will not propel any element if it be present in the soil in greater quantity to the branches than the naked inert limbs referred to by your correspondent, unless on the assumption that the latter travel beyond the range of mere fibre in a downward direction, and pump up water from subterranean wells below. Just for sake of example take a tree of any sort, I care not what, that is being removed, and that is unequally furnished with those naked roots, and take another of equal size that is well supplied with fibre and see which will show signs of active vitality first. Why the latter will grow and flourish long after the former is dead and gone, and for this reason, the fibrous roots become active immediately, and seek out nourishment for the tree at once. The naked fleshy limbs have to wait to make fibre before they afford any support, and while this process is going on the stores of sap in the tree become exhausted, and the tree dies. I am here trying to find a parallel between the power of two supposed sets of roots. Would a tree die if it were even supplied with "crude watery sap" from a source which is supposed to supply it in quantity? Or is it from the incapacity of the power of these roots to supply it that death takes place? One or other of these theories must be correct, and will no doubt be cleared up by some one. The next and only point to which I will at present advert is the supposed potency of root-pruning as a

stood by reference to the annexed plan. This flower garden being laid out in two terraces, the situation is very favourable for this popular style of bedding, as the beds are all in front of the best windows, and being looked down upon have a charming effect, and during the past two seasons have been much admired by all who have seen them. The following are the references to the plan:—A, *Yucca quadricolor*; B, *Echeveria secunda glauca*; C, *Mentha pulegium gibraltricum*; D, *Sedum anglicum*; E, *Alternanthera amœna*; F, *Sedum acre elegans*; G, *Sedum glaucum*; H, *Alternanthera versicolor*; I, *Mesembryanthemum corilifolium variegatum*; J, *Mentha pulegium gibraltricum*; K, *Sedum glaucum*; L, Golden Feather; M, *Alternanthera amœna*; N, *Echeveria secunda glauca*; O, *Teucrium aureum*; P, *Sedum anglicum*; Q, *Mesembryanthemum cordifolium variegatum*; R, *Alternanthera paronychioides*; S, *Echeveria secunda glauca*. G. Silcock, *Somerford Gardens*.

Desfontainea spinosa.—This is a neglected shrub, or one that I believe is adjudged as tender. No doubt a low situation on strong soils does not suit it, but on an elevation of about 100 feet it does well here on a dry, sandy soil, and still better on a dry, strong loam, where at an elevation of 500 feet I have a plant that has obtained a height of 4½ feet, and as much in diameter, having the dark green and to all appearance the hardiness of the common Holly. I think it was about the middle of July that I computed there were from 900 to 1000 of its rich, waxy, yellow and orange blooms out, and I thought it was one of the handsomest, if not the handsomest shrub I ever saw. Last year it remained in bloom until after Christmas.

Cumbrian.

—This plant grows and flowers in the open shrubbery at Broughty Ferry 200 feet above the sea, on ground exposed to all the winds that blow. Last year it flowered in September, this year it came into bloom in August, and now (November 2) two perfect blooms are out and another coming. It has been planted out several years, and has had not a leaf injured by weather, nor has it received a mulching or protection of any sort. D. U.

Flowering of Arundo Donax.—In the *Gardeners' Chronicle* of this and last week your correspondents have stated that *Arundo Donax* has not flowered with them. I have several large plants here which flower most abundantly, and are the admiration of all who have seen them. R. Hanbury, *Poles, Ware*.

The Potato Disease.—It has often struck me as curious, that amongst all the writings upon the Potato disease, no one has suggested the probable manner in which it at least may be perpetuated. It is a common practice here and elsewhere to gather all the haulm, the very rotten Potatoes, &c., and throw all to the manure heap, which is carefully preserved until the time for planting comes round again, then this is carried to the garden or field (in the case of small planters here they never use manure for any other crop), shallow trenches are thrown out, or lazy-beds formed, the manure spread in or upon the surface, the seed laid upon this and then covered with soil. Now from what has been written upon the resting-spores of the disease, a manure heap would seem to offer favourable conditions in which they could hibernate; this being so, the wonder is, not that the disease is perpetuated, but that the noble tuber survives at all. Growers often tell me that they have broken up a new piece of ground upon which most certainly never Potatoes grew before, and yet the first crop is diseased. They quite overlook the fact that they themselves carried it there. Again, a common practice here is to leave the late crop in the ground till November or December—until, in fact, all the bad tubers have disappeared (not so the resting-spores I fancy). Now as many people follow crop after crop for several years upon the same ground, no wonder that there is still *Peronospora* in the country. I am aware that this is by no means the universal practice, but it is very common here. Assuming that some crop other than Potatoes succeeds the latter practice, we know little I believe as to the resting capacities of the spores or their capacity to grow on other plants. Who knows but that if a sack of Potatoes or a glass of water was to get into the British Museum the antediluvian spores lately recorded might not yet wake up. T. Smith. [Mr. Smith's discoveries at once suggested the destruction of the infested haulm, and we have often pointed out its advantages. The antediluvian spores are silicified beyond recovery. Eds.]

Hardiness of Plants.—We often meet with strange examples of the comparative hardiness of various plants. I have two beds of *Fuchsias* growing side by side, one the old Madame Cornelissen, and the other the somewhat newer *albo-coccinea*. The frosts during the early part of October killed the latter quite to the ground, whereas the plants of the former are still (November 3) quite uninjured, with all their leaves and some flowers still on. I know some instances where this last has lived for years on open walls and has become quite large, 6 or 8 feet

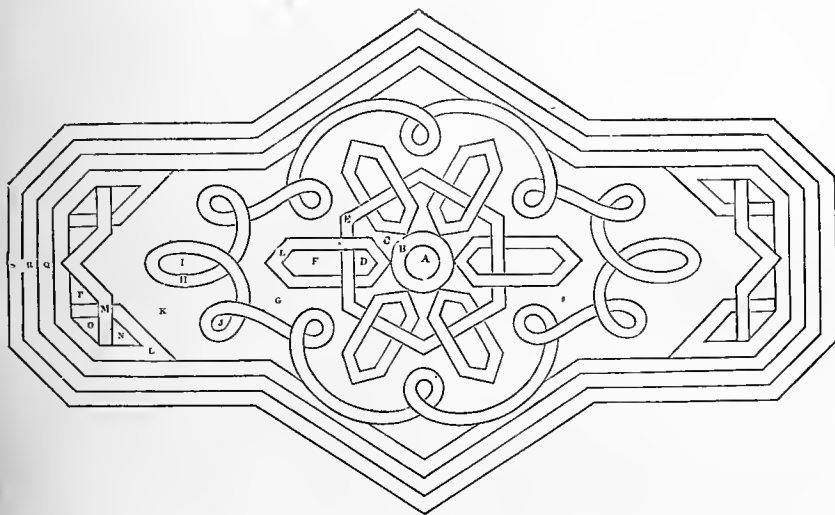

FIG. 118.—DESIGN OF A CARPET-BED AT DOVERIDGE HALL.

past season, and with the performance of the operation itself or the many excellent hints advanced by your correspondent there is little to find fault; there are, however, one or two new theories propounded upon which in a practical sense I am not at all clear, and it is solely with the view of extracting further information that I am tempted to supplement the remarks of "F." rather than to criticise them. The subject, or rather practice, of root-pruning is forcibly advanced by "F.", and few, if any, practical men, can scan over the various points in detail without recalling to his memory some reminiscence of past experience, yet if there be one unsound link in the chain of circumstantial (I cannot call it positive) evidence it disconnects the whole system in a practical light, and leaves nothing but a tottering fabric remaining. The point that seems most inconsistent with present views is that which is either logically or illogically attributed to the functional part or rather power of "big roots" in their relationship as "feeders" to the tree of which they form a part. Does their functional capacity not exceed that of a "self-working water-pump?" or do they supply the tree with no other element than water alone? If in their functional capacity as feeders they supply the tree with other known elements in the same proportion that they are supposed to do water, they are in point of fact the sort of roots that ought to be encouraged; but if, on the contrary, their presence only stimulates a preponderance of aqueous matter which is gathered from unhealthy sources, and that the fibrous roots are the mainstay and life and vigour-producing power of the tree, then we are left to plod in the old track, and have still to abide by what "hard facts" and practice have written down as unmistakable proof of the

means of promoting the earlier and more perfect maturity of the wood and buds. Are we to take this as a benefit to be derived in the current year or not? We have it, I think, plain enough from "F." that the mere cutting away of a few big roots some time in October will lessen the flow of crude watery sap into the branches. This may be so, but will it be in time to assist or hasten maturity? I think not, and would prefer beginning at the other end with a view to accomplish so desirable a purpose, by pinching the strong shoots early in the season, thereby directing the flow of sap into numerous channels, or, in other words, having two or three shoots instead of one. Pinching should be done early, or not at all; and if attended to in proper time, even without a crop, it will lessen the necessity for root hacking which may be requisite in cases of continued neglect, or over-rich soils or shy-bearing varieties; but there can be no earthly pretence for having big watery shoots as long as we have a finger and thumb and the will to use them. W. Hinds.

Carpet-Bedding.—In August last, having occasion to visit some relatives at Doveridge, I called at the Hall Gardens to see the carpet bedding, which more than realised my expectations, and notwithstanding the cold and wet season was looking tolerably well; one bed in particular was very beautiful, and yet when closely examined was found to be composed of plants easily propagated and grown in quantity. Through the kindness of Mr. Povey I am able to give a plan (fig. 118) of the bed and the plants used in the planting. In the centre of the bed was a good specimen of *Yucca quadricolor*, A, with a groundwork of *Echeveria secunda glauca*; but the planting will be best under-

high and proportionately wide, and flowering in the most profuse manner all through the summer. T. Smith, Newry.

Protecting Early Vine Borders.—The time of year is fast approaching for early vineries to be started, and as many are still wedded to the old practice of piling huge hotbeds on the borders it may not be without interest or profit to inquire the why and wherefore of such a proceeding, and whether it is not productive of more harm than good. To follow blindly in the track of our forefathers is to stand still in matters horticultural, and as well might we stick to the old system of dung-beds and heating by means of flues as stifling the roots of Vines by covering them with the enormous heaps of fermenting materials we frequently see used. That they endure it in the way they do year after year only shows that they are endowed with more strength of constitution than most other plants, or they would soon show unmistakable signs of distress, but their power of vitality is such that they struggle on and live through it all, and the treatment goes on without scarce a thought as to the benefits derived. In a natural way we see the buds of trees gradually swelling after the fall of the leaf, and more rapidly as the days lengthen, and yet at that time the ground is cold and wet, and remains many degrees below the heat of the air all the year through. Why then should Vines require to have their roots treated differently to any other hardy plant? That when forced early it is necessary and highly important to keep the frost out of the ground and away from the stems I readily admit, but beyond that, except warding off heavy rain or snow, all else is at least questionable. In a state of Nature in woods and under trees we see the leaves strewn thickly over the ground, where they answer the double purpose of giving back a portion of what has been taken from the soil and of protecting the roots in a most effectual manner. No doubt that these in small quantities would form the best covering that could be used for Vine borders if they could only be kept in position without blowing about, as they would lie light, and being the best of non-conductors would keep cold out and the stored-up warmth of the earth in. It may be objected that forced Vines are not in a natural state, but in reality there is little difference between them and others that come on of their own accord, as the roots simply respond to the call made on them by the application of heat to the tops in the way they do after spring fairly sets in. Vines that are started early every year are prepared for it, as they get part of their season's rest while others are in active growth, and therefore require no extra inducement to get them to start. That bottom-heat is a mistake, and that better Grapes can be grown without it than with it, I feel certain; and so convinced am I of its injurious effects on the border and health of the roots that I have long since abandoned the use of it, and now apply either a thin coating of leaves with a little Bracken strewn over them, or the Bracken alone, and the Vines are now considerably stronger, and finish off better fruit than before. This is not to be wondered at if we consider that during five months when under a hotbed the border is impermeably sealed from the air and borne down under a heavy weight that compresses the soil so close as to render it sodden and sour, but if this were the only ill effect, the summer's sun and a fork-up of the surface might help to set matters right. From close observation I am strongly of opinion that the heat acts much as a fire does when applied to a boiler in setting water in motion in a series of pipes. In the ordinary course sap flows no faster than the slowly swelling buds require it, and to make good the loss caused by evaporation through the pores of the bark, but when heat is applied to a leafless plant the pressure is so great that the sap must perforce find an outlet somewhere, and has therefore to return back through the lower roots, thus keeping up a continuous flow and return. [Is this fact or theory? Eds.] The effect is as exhausting as bleeding that takes place after late pruning, or even more so, as they are then quickly in leaf, and the sap after that is utilised and passes on through its proper channels in a natural way. It is not long since a great stir was made about heating Vine borders from below by a series of hot-water pipes, and many went to much expense in having arches built or chambers made in which to place them; but what has come of it all? and where can any of these costly appliances now be found in use? At St. James' Hall many years ago I remember seeing three bunches of the most perfectly finished Muscats I have ever met with, which came from The Denbies near Dorking, and which were said to have been cut from Vines growing in a border heated from below in the above manner, but with that exception I have seen nothing resulting from them that would in any way recommend their adoption. Those three bunches of Muscats created such a furore in the Grape growing world at the time that all were anxious for borders constructed and heated in the same way, and many were the visions indulged in as to the future of Grape growing on that plan; but time has since

proved, by the more sensational bunches that have recently been exhibited, how fine they can be grown without any such aids. If bottom-heat were necessary or in any way beneficial, there can be no question that its application from below by means of hot-water in either tanks, gutters, or pipes, is the right mode of using it, as then the aëration of the border is not interfered with in the way it is when a mass of stable-manure and leaves are laid on the top. The importance of the sweetening influence of the atmosphere on soil and its beneficial chemical effect on the same is now generally recognised, and it is found that ground on which the light and air does not act soon becomes unfit for the roots of plants, as is clearly shown when they happen to be growing in dirty pots or under concrete, as was once tried for Vines. I remember some twenty-five years ago this came in fashion, and many borders were coated over with an impervious plaster that was expected to work wonders by drawing heat from the sun, thus giving it without cost or labour. This, perhaps, it did, but like the huge hotbeds in use it excluded the air, and tenacious of life and long-suffering as the Vine is it was not slow in resenting such treatment, and its use had to be abandoned, as under it roots languished and died from the soil becoming close and inert, and Grapes that used to colour like Sloes assumed that puce-red shade which is a sure index that the food supply is either deficient in quantity or quality. There are few of us who would think of laying a heap of strongly fermenting manure over the roots of a favourite tree, as we should expect by so doing to injure its health, and yet we put on a Vine border what we should hesitate to throw as a convenience elsewhere. Although I have never been to Combe Abbey I am informed that Mr. Miller, who, as is well known, grows some of the best Grapes that are produced, not only does not use any fermenting material at any time, but does not ever cover his borders in winter. No doubt he has a good soil and plenty of drainage, which gives natural warmth to the border, and quite as much of it as Vines require. If perchance the temperature is lowered by snow-water or rain passing through, the air, which quickly takes the place of moisture, soon raises it again to a sufficient degree to suit and encourage healthy root-action. S. W.

The Ash of Celery.—The ash of Celery is so unlike in its composition all other plants of which any analysis has come under my notice, that I give it here just to show how one may err in the application of manure when one has no data to guide them in their treatment of different subjects. It differs from any other plant in having a very much larger percentage of potassium and chlorine. The composition of ordinary stableyard manure approximates pretty closely to the composition of an ordinary rotation of kitchen-garden crops, especially when the farmyard urine is utilised in the garden. There is a loss of silica, no doubt from the fact of it being present in a great percentage in straw, but that is not considered worth troubling much about; but as regards the Celery crop the difference between the wants of that plant and the mineral salts supplied in ordinary stableyard manure is so great as to cause the loss, as far as regards the Celery crop, of nearly everything save potassium and chlorine. Here is the analysis:—

Potash..	22 07
Magnesia	5 82
Lime	13 11
Phosphoric acid	15 58
Sulphuric acid	5 58
Silica	3 85
Phosphate of iron	2 66
Chloride of potassium	33 41

Now there are actually a few garden products with as great a percentage of potassium as here, but as these substances are not of much account here, we must compare the wants of Celery with the food usually given. Ordinary stableyard manure supplies everything named in tolerable abundance except these, and, as we know the value of the manure is just according to the presence of the substance most wanted, it follows, then, that whatever manure we give to Celery will only feed that crop as far as potassium and chlorine in an available form may be present. As the percentage of these in stableyard manure is too little, it follows that the addition of these alone will equal in value a further addition of stableyard manure. Let us suppose, then, that Celery planted in the usual way is going to get a soaking of manure-water, what should we give? The answer is very simple. Cow urine is very rich in the salts of potash, but still with this chlorine is still wanting. Common salt (chloride of sodium) supplies this want, but care must be exercised in its use. All the salts put together contained in the plants of a trench of Celery when full-grown does not amount to much, and the chloride of potassium, it will be observed, only forms a little over one-third of the whole ash. My own practice is to make a manure-water for Celery of cow urine one part, pure water four parts, and to each canful of water I add about half a teaspoonful of common salt, and I am quite satisfied with the re-

sults. In very wet weather we make it more concentrated, and when very dry more dilute; but in the latter case we flood the trenches. I may add that I find common salt, applied in this way, or by sprinkling very slightly during rainy weather, to have a very beneficial effect on all the Brassica tribe of plants, but our situation is inland and subject to bleaching rains, and this has to be taken into account as the rain which fall in certain places, East Lothian for instance, carries more salt to the land than can possibly be removed by the crops. A. H.

Asparagus Dregeanus.—I send you a small spray of *Asparagus Dregeanus*, a lovely species. The stems are procumbent, hanging over the edge of the pot on a shelf, and bearing profusely the charming white, red-stamened flowers, and literally perfuming the house. What a chaste and beautiful fringe this would be for a bridal bouquet. T. Smith. [A very elegant plant. Eds.]

Orchids in October.—The following have adorned the show-house during the month of October:—

<i>Cattleya superba</i>	<i>Masdevallia ochthodes</i>
„ <i>marginata</i>	<i>Dendrobium cucullatum</i>
„ <i>bicolor</i>	„ <i>secundum</i>
„ <i>maxima</i>	„ <i>chrysanthum</i>
<i>Lælia Perrinii</i>	„ <i>palpebræ</i> (bicolor)
„ <i>Dayi</i>	<i>Epidendrum stratum</i>
<i>Mithonia caudata grandiflora</i>	„ <i>aromaticum</i>
<i>Odontoglossum Alexandræ</i>	<i>Cleisostoma latifolia</i> (worthless)
„ <i>Rossii majas</i>	<i>Rodriguezia</i> species (a spike of
„ <i>grande</i>	small flowers in shape
„ <i>angustatum</i>	same as <i>R. secunda</i> ,
„ <i>Bluntii</i>	but a pale yellow)
<i>Pleione lagenaria</i>	<i>Cœlogyne brunnea</i>
„ <i>Wallichii</i>	<i>Lycaste Skinneri</i>
„ <i>biflora</i> (new)	„ <i>lanipes</i>
„ <i>maculata</i>	„ <i>leuco-flavescens</i>
<i>Zygotetulum œruleum</i>	<i>Scuticaria Hartwegii</i>
„ <i>intermedium</i>	<i>Stanhopes Wardii</i>
„ <i>Mackayi</i>	<i>Cypripedium niveum</i>
<i>Bifrenaria aureo-fulva</i>	„ <i>Koziui</i>
<i>Oncidium Rogersii</i>	„ <i>longifolium</i>
„ <i>tigrinum</i>	„ <i>barbatum</i>

Edward W. Cox, Moat Mount, Mill Hill, Nov. 3.

Seedling Calanthes.—In the gardens of C. Baring, Esq., at Winkfield, near Windsor, there is an immense quantity of seedling *Calanthes*, which have been raised in a very simple but yet uncommon manner. The parents are fine plants of *Veitchii*, of which there are a large quantity and all remarkably healthy. These flowered last season most profusely, and produced seed in abundance. The seed-pots were allowed to hang until May last when they burst, and being so arranged that the seed could drop on the neighbouring pots, they commenced coming up in July in great numbers, and continue to do so; those which first appeared are now just commencing to form their bulbs. Besides these many other Orchids are being raised from seed here, including *Cypripediums*, some of which are sufficiently advanced to produce flower-spikes; some of them promise to rank At amongst future varieties of this beautiful class. Mr. Baring takes very great personal interest in the crossing and raising of these in particular, and devotes a great deal of time to them, besides sparing no expense to procure the very best. *Odontoglossum* crossed with *Zygotetulum* is a new feature here, which promises to give some novelties. Amongst those in flower specially worthy of notice might be mentioned an extremely fine plant of *Mesospidium vulcanicum*, *Odontoglossum bictoniense*, with spikes 4 feet long; many fine plants of *Odontoglossum grande*, a beautiful piece of *Oncidium varicosum*, *O. Papilio majus* and *Kramerii*, *Stanhopea Wardiana*, *Dendrobium album*, with bulbs 4 feet long, flowering almost their entire length; and last, but not least, a magnificent specimen of *Peristeria elata* (the dove flower), with thirty flowers on seven spikes. Although Orchids are undoubtedly the *specialité* here gardening generally is carried on with much spirit. The kitchen garden is good, and the flower garden second to none in the neighbourhood. The whole is under the careful management of Mr. Staddon, H. R. J.

Another Plea for the Neglected Tree.—On reading "P. P. C.'s" plea for the beautiful deciduous Cypress, I was astonished to find he never so much as alluded to the rich and splendid autumnal tint it not only assumes but retains longer than most other trees. As I turn my head from the gardeners' *Chronicle* to the window my eye falls upon a specimen about sixty years old, a perfect cone, about 33 feet high, its graceful branches being densely

covered with reddish-brown Fern-like foliage; and standing as it does in the midst of the golden-tinted Tulip tree and Aspen Poplar, the sombre green of the Yew, Box, and Rhododendrons, and the Aralia japonica, with its large exotic-like foliage and white flowers, it forms a striking and beautiful object. "P. P. C.'s" concluding remarks seem to imply that the delicious Cypress is somewhat tender, and particular as to soil; meanwhile the one he speaks of is growing on stiff but dry clay soil, the one I have described is growing in a light sand, but only 6 or 7 yards from a well, and I know of two other trees about the same size, one growing on a light sandy soil, inclined to peat, the other on a small island, with the water only a foot or so below the surface, and in a low situation that must be very much subject to frosts: the other two trees stand higher, and exposed to the east wind, which they stand better than most of our common trees. *Cumbrian*.

Bicoloured Gymnogramma.—I send you along with this what to me seems a most extraordinary occurrence—a Gymnogramma frond with a golden back, cut from a plant of *G. tartarea*, which has, as every one knows, silvery backs. I was to-day cutting some Fern fronds, and on cutting this happened to notice the colour, and immediately examined the plants (three in number), but could not find any other trace of gold. It is quite impossible that any mistake could have been made, as we have no golden Gymnogramma at all upon the place. *T. Smith*. [Such freaks are not uncommon, but we do not know the cause. *EDS.*]

A Good Late Melon.—To those wishing for a good-flavoured late Melon, I would recommend Victory of Bath. We have been cutting that variety here the past few weeks (pronounced by my employer excellent), and grown alongside with Eastnor Castle, it proves far superior in flavour to that variety. I cannot speak so highly of Dr. Hogg's your correspondent, p. 436. If I grew but one green-fleshed it would certainly be Victory of Bath. *C. H., Chalfont Park, Slough, November 5.*

A Plea for the English Ivy.—I have often wondered how it came about that our beautiful native Ivy (*Hedera Helix*) should have been thrust aside in favour of its more robust, but coarser relative, the Irish variety. That the latter is a bold, quick growing, handsome, evergreen climber, is allowed; but in no whit is it better, or in my opinion so handsome as our native plant. People who only see the native plant trailing along the ground, in the hedgerow, or the wood, with its small palmate leaves, may have no idea of its appearance or the proportions it will assume under cultivation or favourable circumstances for development. It is the native Ivy that lends the charm, and I may add the poetry, to most of the remains of our old castles, abbeys, and other ruins: take away their Ivy and their charm is gone; and imagine a ruined tower clothed (or smothered) with Irish Ivy, compared with one mantled over, or partially so, with our native plant. The Irish Ivy differs from the native just as a Pumpkin differs from a Melon, it being larger and coarser only. However beautiful the Irish Ivy may be, its great fault is that the leaf-stalks are over long, and where cultivated on walls, dwellings, &c., must undergo an amount of clipping which renders it for a long time like a sign-board without reading, while the native kind seems a part of the stone or rock on which it grows, and will have twenty leaves for the other's one. So much for the prejudice in discarding, perhaps, the most beautiful of our native plants. Let me assure those who are about to plant Ivy, whether as an ingredient in panel or geometrical gardening, or for whatever purpose employed, with the same amount of care the English Ivy will be far more satisfactory than its rival, and humble as it may seem, there is no known limit to its growth. There are in the neighbourhood of Banbury immense Poplar trees fully 100 feet high smothered with it. I have been induced to put these remarks together from the fact, that while scarcely enough Irish Ivy is grown to meet the demand, our native Ivy is seldom inquired after. *T. Williams, Ormskirk.*

Callas or Richardias.—These are largely grown for the London market, and there are few plants that are more appreciated, either as pot plants or as cut flowers. It seems to be a favourite window plant among the working classes, who prize their "white Lilies." Like other hardy plants, it is easily grown and well repays liberal treatment; it is propagated by the small bulb-like offsets formed on the old roots: they are picked off as small as Peas, and are grown on in well prepared beds till strong enough to pot for market. Early in October all the stock is lifted and sorted into sizes, after picking off all the offsets. The strongest roots are potted, generally into 4-inch pots, in a compost of loam and a little dung and sand, and set in a cool pit or house, where they can be shaded for a few days and receive liberal syringings till they

begin to grow, when they should receive all the air possible. Some growers pot them in the spring and plunge them, which I think is the preferable way for small quantities, as they do not go so much to leaf, and do not receive such a check at lifting time; they flower quite as freely and are more easily forced, as the pots are full of roots. They are introduced in batches into an intermediate house as required, and are not generally started very early, as they are apt to go blind if started much before Christmas. It is here that those plunged have the advantage, as they often show flower early in the season. The smaller roots are sorted into sizes at lifting time, planted thickly in boxes and grown on in a cool house, where they can be protected from frost; in May they are all planted out and, with liberal treatment, it is surprising how soon the smallest offsets make marketable plants. In private establishments it is not grown in quantity nearly so much as it deserves to be, for as a cut flower for vases it has no equal. *E. W.*

The Wilson Raft.—I have been asked, What is doing with the "Wilson raft?" Will you allow me to answer this question in your columns? The "Wilson raft" has done what I hoped for from it—it has shown after more than a year's trial that water-plants, bog-plants, and moist-soil plants, can in an ordinary garden be grown thoroughly well side by side. The one trouble I have had is from water-logging: as the wood of which the raft is composed becomes more and more saturated with water it of course becomes less buoyant, and sinks deeper and deeper. A relative who has seen much service in India suggested a pontoon. Carrying this idea out further, we propose to get rid of all question of saturation by having the raft, supports and all, made of metal. We have a photograph which shows the raft with its growing plants fairly well; and as a thoroughly competent engineer has now taken up the matter, I hope soon to have a working drawing of an inexpensive practical metal raft which will answer every purpose. I shall then send you these two, in the hope that you will think them worthy of being engraved for the *Gardeners' Chronicle*. My friends have taken care that I shall not be uplifted by the invention. They impress upon me that the idea is not new. One of the first I spoke to on the subject—a horticulturist of great experience—thought very highly of the notion, and at first thought it quite new, but afterwards recollected that the Persians grew Melons on something like rafts. Mr. Taylor, one of the most experienced of Messrs. Veitch's staff, when he first saw the "Wilson raft" in operation, exclaimed, "How simple—and how odd it never occurred to any one before!" Mr. Roger, the able superintendent of Battersea Park, tells me that he grew some plants on a float years ago. One friend told me point blank, "You know the raft is not new. The Chinese grow trees on floating islands." I care little whether it be old or new. One thing is, I think, certain—that practically rafts are not used, at any rate to any extent, in this country; I mean that the "Wilson raft" shall be largely used, and expect that many lovers of very beautiful tribes of plants will thank me for having called their attention to a simple means of growing them. *George F. Wilson.*

A Plea for Herbaceous Plants: Carpet Bedding.—I think it will be admitted that your correspondent, Miss Hope, is rather severe in her criticisms on carpet bedding and on the paucity of herbaceous plants to be seen in botanical and other gardens. If it be admitted that "all fashions" are necessary in public parks, why so much severity against that which has been admitted on all hands as an attractive feature in such places?—and as all the attempts at carpet bedding which Miss Hope has seen, except at Clapham, Victoria Park, and Battersea, have been but caricatures of those places, I think it proves that some skill is necessary to copy "artificial carpet bedding." It does not appear that your correspondent is very clear on the subject of herbaceous plant borders, and evidently cannot trust to such plants making an effective display of themselves, for in the remarks made it is suggested that, "between each strictly herbaceous plant there should be a prominent plant of interesting habit or foliage;" then the names are given of such trees as are considered suitable for the purpose. It is then apparent that it is not to be an herbaceous border after all, but a tree and shrub border supplemented by them, the shrubs and trees to be permanent and effective—two qualities not obtainable in herbaceous plants. Thus the reason why their cultivation is not more extensive. A little further on Miss Hope goes on to describe an effective mixture of pillar Roses, Clematis, &c., still further proving that herbaceous plants, for whom such an earnest appeal is made, are only to play second fiddle in a display which no one doubts can be made very satisfactory. I have seen a number of herbaceous beds and borders, but never one such as your correspondent describes as not being "torn up at the first frost;" this may be so in a sense, for as a rule there is little left in an herbaceous border to be torn up when the frost comes. *George Thomson, Crystal Palace, S. E.*

Reports of Societies.

Royal Horticultural: November 6.—Sir Joseph Hooker, C. B., President, took the chair at the SCIENTIFIC COMMITTEE.—Dr. M. C. Cooke made the following communication on "Diseased Mulberry Leaves." On September 3 some diseased Mulberry leaves were sent by Mr. Lee, of Cleveland, to the secretary of this committee, who forwarded them to me for examination and report. The letter which accompanied them stated that the leaves of the writer's Mulberry trees had been attacked by some fungus for four or five years. It made its appearance on the south side of the most southerly tree in the first year, and did not spread over the whole tree, nor until last year did it affect the whole of the trees (six in number) where it first appeared, and also ten others at a distance of some 300 or more yards. This year the first spots appeared about the middle of August. Subsequently I wrote for a further supply of leaves which had the disease a week older, and in sending these Mr. Lee remarked that the disease did not spread so rapidly this season as it had on previous occasions, probably on account of the coldness of the weather. The leaves are disfigured by orbicular discoloured whitish spots, with a broad purplish margin. Each of the spots is occupied in the centre by a small, dark brown, immersed perithecia, which exudes a large quantity of uncoloured spores through a perforation at the apex, and these accumulate on the surface of the spots, giving them a white mealy appearance. The spores are cylindrical, obtuse at the ends, usually slightly curved, and ultimately having about five septa. It is most undoubtedly *Septoria Mori*, described by Leveillé some years ago, which is common throughout the Continent of Europe, and extends to the United States of North America. I have compared the specimens, by the kindness of the Rev. M. J. Berkeley, with authentic specimens in his herbarium communicated by Dr. Leveillé himself, as well as with specimens from other parts of France, Germany, Italy, and North America. I was led to extend this examination and comparison, because in his original description Leveillé makes no mention of the septation of the spores, which was very marked in the Clevedon specimens. I find, however, that although the majority of spores exuded on the surface of Dr. Leveillé's specimens have no distinct septa, that some of them have the endochrome divided, and in a few the septa are formed. It must be confessed that this could not be seen with the spores in their natural condition, but when stained by roseine they at once become manifest. Leveillé not having resorted to this mode of examination overlooked the septa, and hence the discrepancy. The fresh specimens from Clevedon offered spores with septa so distinct that no staining was necessary. The spores measure .035—05 × .003 mm. When first describing this species in the *Annales*, Dr. Leveillé distinctly intimates that the species is probably of a deleterious or destructive character. Mentioning the subject to Dr. Maxime Cornu during my recent visit to the fungus meeting in Paris, he remarked that though extremely common he was not aware that it was considered injurious to the trees themselves, although the theory had been promulgated that this disease of the leaves was the cause of the silk-worm disease. It need not be added that this theory has no solid foundation.

The experience of Mr. Lee shows that this parasite has a tendency to spread itself in succeeding years, and from this locality, the first recorded in Britain, it is probable that it will now extend itself over the country, as *Puccinia malvacearum* has done. It is just probable that had he collected and burnt all the diseased leaves which appeared the first year that the invader would have been vanquished, but it is doubtful whether it has not established itself now too firmly to be easily dislodged.

A singular circumstance in connection with these leaves at first complicated the examination very much, and greatly increased the difficulty of determination, this was the association of other fungi with the *Septoria*. Nearly every spot had its centre blackened by some parasite which it was ultimately found had no relation whatever to the original disease, but was referable to a quite distinct family and genus. This parasite consisted of cylindrical spore masses, with a short stem and almost always obtuse apex, from .05—07 mm. long, divided by numerous septa, constricted at the joints, and torulose, of a clear brown colour when mature, reminding one strongly of the spores of *Zenodochus* on a reduced scale. I have no doubt that this is an undescribed species of *Sporidesmium*, to which I have applied the name of *Sporidesmium parasiticum** allied to *Sporidesmium exitiosum*,

* *Sporidesmium parasiticum*, Cooke.—Parasiticum, atrum, sporis breviter septatis, multi septatis, torulosis, brunneis, .05—07 mm. long, .01 mm. lat. In pustulis septoriæ ad foliis Mori.

Kuhn, but entirely and manifestly distinct, as I convinced myself by an examination of specimens in the herbarium at the Jardin des Plantes. This is manifestly a subsequent growth to the Septoria, is in no sense the cause of the discoloured spots, and would not affect the health of the tree.

In order to illustrate the rapid manner in which other fungi take possession of diseased spots I may remark that, in addition to the Sporidesmium, a species of Cladosporium, allied to Cladosporium epiphyllum, was found on some of the pustules, and in one or two instances I feel convinced that some Cercospora was present, but the better establishment of this fact would have occupied considerable time, and it evidently was not the prime cause of disease. In the genus Cercospora the spores are borne on short hyphae, which are entirely free, and not enclosed in perithecia as in Septoria. In the present instance the spores were almost identical in size with those of the Septoria, the only appreciable difference being that the former are attenuated upwards, whilst the latter are uniform; this difference is so slight that only their mode of generation could be taken into account, and although I feel tolerably certain that I found the spores simulating Cercospora growing in fascicles on free threads, this circumstance requires confirmation before it can be positively affirmed.

New Vine Disease.—Dr. M. C. Cooke also showed specimens of a Vine disease which has lately appeared in some parts of France, and has given rise to some anxiety. It is the result of the attack of a fungus, *Phoma viticola*, and will be made the subject of a further report on another occasion.

Phyllotoma aceris.—Mr. MacLachlan alluded to the curious little discs cut out of the leaf of Maples by this insect, which was figured and described in our columns on August 26, 1876.

Gall on Oak, &c.—Rev. Geo. Henslow showed a fleshy gall on an Oak from Italy, and a section of Oak showing a pulley completely embedded in the timber, with no trace on the outside of the original injury.

Miscellaneous Exhibits.—Dr. Masters showed from Mr. Harrison Weir a multiple Grape, originating from the fusion of two or more berries. 2. A Grape within a Grape, sent by Mr. Thomson, of Clovenfords. The adventitious Grape occupied the position of a seed, and was only rendered evident by the cracking open of the parent Grape. 3. A root of Brassica Rapa raised from seed received from Professor Caspary, of Koenigsberg, and presenting the peculiarity that the root was studded with tubercles, some of which developed into adventitious buds. The plant was figured in the *Gardeners' Chronicle*, 1877, p. 149, vol. vii. The hereditary tendency is thus seen to be marked. 4. Various malformations, concerning some of which a further report will be forthcoming.

Sir Joseph Hooker's Trip to the Rocky Mountains, &c.—Sir Joseph Hooker then gave, in a few words, an outline of his recent trip in the Rocky Mountains, Colorado, and California. The main object of the trip was to trace the geographical distribution of plants, especially of trees, in America, to study the Conifers of California to settle their synonymy, &c. Great attention was paid to the young plants, as they were found in many cases to be extremely variable, even where the adult trees of the same species were relatively constant. Sir Joseph then entered conversationally into a few details relating to *Picea nobilis* magnifica, *Pinus tuberculata*, *ponderosa*, *Jeffreyi*, *Balfourii*, *Cupressus macrocarpa*, and several others—details of very great interest, which when arranged for publication we shall have the privilege, thanks to the courtesy of Sir Joseph, of laying before our readers. The thanks of the meeting were awarded to the President for his interesting communication.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. The room was fairly well filled to-day with cheerful and attractive flowering plants; and there was a good muster of committeemen, but owing to the inclemency of the weather but few visitors put in an appearance. Messrs. James Veitch & Sons contributed by far the largest group of plants, principally Orchids, and a very striking group it was for the season. The committee recommended the award of a medal, and granted First-class Certificates for a new Tree Fern from Juan Fernandez named *Dicksonia berteriana*; and for *Sarracenia chelsoni*, a hybrid between *S. rubra* and *S. purpurea*, and much resembling the first named parent. Amongst the Orchids were nice fresh flowering examples of *Odonoglossum Roezlii*, *Pleione lagenaria*, *maculata*, and *Wallichiana*; the singular little *Stelia Bruchmulleri*, *Calanthe vestita rubra*, *Veitchii superba*, *Sedeni*; *Oncidium varicosum*, *Cypripedium oenanthem*, *selligerum*, *Crossianum*, *tessellatum*, *marmorophyllum*, *Arthurianum*, *Ashburtoniae*, *Sedeni*, *insigne*, *Maulei*, and *Schlimii*; *Cattleya marginata* and *labiata*, *Laelia Perrinii*, and *Oncidium Weltoni*, *crispum*, and *incurvum*. Besides these there were flowering plants of the pretty *Vreisia brachystachys* and the singular *Pavonia Wiotti*, together with *Pelargoniums* Amazon, scarlet; *Egeria*, rosy crimson; *Atlantia*, cerise; and *Heather Bell*, pink, with white centre—all of Dr.

Denny's raising; also the dark rosy crimson-flowered *Eranthemum laxifolium*, an introduction from the South Sea Islands, &c. Mr. Ollerhead, gr. to Sir Henry Peck, M.P., received a vote of thanks for a showy group of Orchids, which included *Calanthe Veitchii* and *vestita rubra*, *Oncidium pulverulenta*, *Cypripedium Sedeni*, *Odonoglossum bictoniense*, and *O. Roezlii*, *Pleione lagenaria* and *P. Wallichiana*, *Lycaste Moreliana*, *Lycaste Skinneri*, and *Cattleya Dowiana*. Mr. W. Smith, gr. to C. Lane, Esq., Badgemore, Henley-on-Thames, exhibited a magnificently flowered specimen of *Vanda cœrulea*, which was recommended for the award of a medal. It had two fine growths, on which were six spikes and eighty-nine flowers. Sir Trevor Lawrence, M.P. (Mr. Spyers, gr.), showed a grand specimen of the dark-flowered *Oncidium crispum* with half-a-dozen remarkably fine spikes of flowers—a Cultural Commendation was awarded. Mr. H. B. Smith, Ealing Dean, received a vote of thanks for a nice group of Cyclamens; and Mr. R. Parker, Tooting, a similar acknowledgment for a very choice collection of cut flowers of various hardy herbaceous plants, which included a dozen species of the showy Asters, such as *A. multiflorus*, *horizontalis*, *ericoides*, *laxus*, *Amellus*, *novæ-belgii*, *Reevesii*, *pendulus*, *discolor*, *novæ-angliæ*, *spectabilis*, &c.; also examples of such fine bedding varieties of *Chrysanthemum indicum* as *Scarlet Gem*, *Madame Pecoul*, *Hendersoni*, *Cassy*, and *Frederick Pell*; and *Lithospermum prostratum*, *Helleborus niger maxima*, *Trollius asiaticus*, *Aponogeton distachyon*, &c. Messrs. E. G. Henderson sent a dozen blooms of Japanese *Chrysanthemums*—all distinct, and of fine quality. A vote of thanks was awarded. Mr. Cannell, Swanley, sent a couple of dozen bunches of flowers of various Zonal *Pelargoniums*, fine in size, fresh and bright in colour. From the Society's gardens, Chiswick, Mr. Barron sent up a dozen plants of an exceedingly pretty mauve or lilac-flowered *Primula capitata*, an alpine species with farinose stems, which was awarded a First-class Certificate. A good specimen of Major Clarke's new *Begonia Moonlight* was also sent from Chiswick, to show what a grand plant it is for winter flowering. Mr. R. Dean, Ealing, received a vote of thanks for a plant of the new *Godetia Lady Albemarle*, lifted from the open ground, and flowering very freely in a pot. The plant was dwarf, and the colour of the flowers very bright and fresh.

FRUIT COMMITTEE.—H. Webb, Esq., in the chair. A few very meritorious productions came under the notice of this committee, amongst them being two bunches of Muscat of Alexandria Grapes of unusually high quality, considering the season. They were of good size and form, fine in berry and colour, and absolutely without spot or blemish of any kind. The exhibitor was Mr. Atkins, gr. to Colonel Lloyd-Lindsay, M.P., Lockinge Park, and the committee recommended the award of a Bronze Medal. Mr. J. Dinsmore, gr. to J. F. Blackwell, Esq., The Cedars, Harrow Weald, sent a very finely developed Charlotte Rothschild Pine, weighing perhaps between 8 and 9 lb. A vote of thanks was accorded. Mr. J. Hudson, The Gardens, Gunnersbury House, Acton, was awarded a Cultural Commendation for a particularly good dish of Golden Ham-burgh Grapes. The same exhibitor also showed half-a-dozen handsome Queen Pines of the aggregate weight of 27½ lb., and the award of a Silver Medal was recommended. Mr. C. Tyler, gr. to W. R. Gosling, Esq., Hassobury, Bishop Stortford, again sent a specimen of his seedling green-fleshed Melon named *Exquisite*, which proved to be of excellent quality and was awarded a First-class Certificate. Mr. Harrison Weir, Weirleigh, Brencley, contributed a capital sample of Muscat Champion, considering that it had been grown in a ground vine; also some large bunches of Mrs. Pince's Black Muscat. Mr. Gilbert, gr. to the Marquis of Exeter, Burghley, sent a sample of his Improved Early Brussels Sprouts, which was much admired for its evidently fine quality. The strain is undoubtedly a good and useful one. Mr. Wildsmith, gr. to Viscount Eversley, Heckfield Place, exhibited a fine dish of Gros Colman Grape, the berries being of enormous size. Mr. Tillery, Welbeck, sent half-a-dozen fine Salway Peaches, and Mr. Bennett, of Rabley, a dish of ripe Garibaldi Strawberries. New varieties of Apples were shown by Mr. Penny (of Sandringham), Mr. Douglas, and Mr. Gilbert, but the committee made no awards to either of them. Mr. R. Dean sent a specimen of his Excelsior Long White Marrow and samples of a dozen varieties of Potatos; and Mr. J. B. Wilson, Claydon House Gardens, half-a-dozen good specimens of Veitch's Autumn Giant Cauliflowers. Messrs. Hooper & Co., Covent Garden, showed, on behalf of Messrs. Bliss & Sons, of New York, a collection of nineteen dishes of American Potatos. Messrs. James Carter & Co. exhibited a very large collection of Potatos, in which the samples were of much superior quality to what this and other seed firms usually exhibit. The committee recommended the award of a silver Banksian Medal to Messrs. Carter. From the gardens at

Chiswick came about two dozen varieties of Turnips which have been under trial there this season, and of which we shall, no doubt, soon have an official report.

Natural History.

OAK GALLS.—During the present season I have been fortunate enough to find a few species of Oak-galls either previously unnoticed as British, or of such rarity that I should be glad to add a note of their occurrence in the neighbourhood of Isleworth to the paper on Oak-galls of 1876 in your number for October 13.

In the beginning of March of the present year I found galls of the *Aphlothrix corticis* (which had not previously been observed in Britain) in large numbers on an old Oak in Osterley Park. These galls may previously have been overlooked from their resemblance in their early and later stages to those of the single-celled form of *Aphlothrix radialis*. They are similarly about a quarter of an inch long, narrow, fang-like below and round-topped above, and similarly also to be found in young bark forming over an injured surface, such as an amputated limb or the riven channel of a flash of lightning, but in middle life the distinction between the two species is clear.

Then the *Aphlothrix corticis* galls appear as in the figure (fig. 119, magnified); the round top dies, decays, dries, and shrivels itself off (as in the upper figure), or may be lifted off, showing (as in the lower figure) the more permanent part of the gall with its circular sharp-edged mouth, closed inside by a convex woody cap, fitting into it like an inverted saucer in a Chinese teacup.

The *Aphlothrix* effects its escape by piercing an aperture through this internal diaphragm or secondary

EO

FIG. 119.—APHLOTHRIX CORTICIS.

top, and as long as this remains the gall is clearly recognisable.

Another gall is still more interesting from occurring on the Turkey Oak (*Quercus Cerris*), which had previously been considered free from gall-growths in England.

Of these galls I found a very few last year, mostly in a much injured condition, on a tree of *Quercus Cerris* and one of *Q. Cerris* var. *Lucombeana* in the Royal Gardens, Kew. Early in the present year I again found this minute bud-gall on the same specimen of *Q. Cerris*, the galls for the most part empty, but with the insect in two cases enclosed so as to allow of it being determined as a hitherto undescribed species. The galls are only about the sixteenth of an inch in length, somewhat linear, completely rounded below, and terminating in a blunt point above, single chambered and thin walled, and placed in groups of two or more amongst the linear stipules, and though fairly numerous on this one tree of *Q. Cerris* difficult of detection from their extreme minuteness.

I may also add to the list of suburban Oak-galls one or two specimens of the scarce *Spathogaster vesicatrix*, a small circular gall affecting both sides of the Oak leaf, flat above, with a central point, and rays radiating from it, and convex on the under surface of the leaf. This gall has only recently been noticed as a British species. It has been found (*Entomologist*, No. 173, p. 251), by Professor Trail, at Banchory, and I have also found it in some small numbers at Sedbury Park, near Chepstow, in 1873.

The *Neuroterus fumipennis*, one of the scarcer species of Oak-spangle, distinguishable by its minute saucer-like form, and glabrous surface, pale green tint, and sometimes rosy rim, has been unusually plentiful this autumn, and the very rare allied species, *N. lævisculus*, somewhat saucer-shaped also, but of a

whiter tint and covered inside and outside with scattered pencils of brightly coloured hairs, has also been represented in the neighbourhood of Isleworth. O.

WITCH KNOTS ON THE BIRCH.—In the early part of the present year two interesting articles appeared in your paper (vol. vii., new series, pp. 249 and 281) on the curious witch knots found on the Birch. At Wallington, in Northumberland, the seat of Sir Walter Calverley Trevelyan, there is one of the most remarkable specimens which I have ever seen of the pendulous variety of the silvery-stemmed Birch (*Betula alba pendula*) covered with these witch knots. There are upwards of fifty of the "knots" on it, of various sizes, some being so large and compact as to look at a little distance like rooks' nests hanging from the slender branches. The tree (which has been planted about fifty years) has so curious and striking an appearance that it would be worth while to have a photograph taken of it. Close to this tree there is another of the same kind of Birch, of similar size and age, but, oddly enough, only two or three slight indications of "knots" are at present discernible on it. D. W.

- Nov. 1.—A fine bright day. Partially cloudy till evening, then cloudless.
- 2.—Fine, but cloudy till evening. Overcast, and a little thin rain fell at night.
- 3.—A fine day, partially cloudy. Cool breeze.
- 4.—Fine and clear till 10 A.M., dull and cloudy after. Thin rain at 11 P.M.
- 5.—A very fine day. Cloudy at times. Mild.
- 6.—Overcast and dull throughout. Mild. Frequent rain.
- 7.—Overcast, dull and wet till 1 P.M. Fine, but very cloudy after. Mild.

LONDON: Barometer.—During the week ending Saturday, November 3, in the suburbs of London the reading of the barometer at the level of the sea increased from 29.90 inches at the beginning of the week to 30.16 inches by the evening of the 28th, decreased to 29.62 inches by the evening of the 29th, increased to 29.87 inches by the morning of the 30th, decreased to 29.66 inches by the evening of the same day; increased to 30.42 inches by the afternoon of November 1, decreased to 29.93 inches by the evening of the 2d, and increased to 30.14 inches by the end of the week. The mean reading for the week at sea level was 30.06 inches, being 0.38 inch above that of the preceding week, and 0.11 inch above the average.

Temperature.—The highest temperatures of the air observed by day varied from 61½° on October 30 to 53½° on November 3; the mean value for the week was 56½°. The lowest temperatures of the air observed by night ranged from 37° on November 2 to 47½° on October 31; the mean for the week was 42½°. The mean daily range of temperature in the week was 14°, the greatest range in the day being 19°, on November 2, and the least 9°, on October 31.

The mean daily temperatures of the air were as follows:—October 28, 50° 3; 29th, 51° 4; 30th, 51° 6; 31st, 51°; November 1, 47° 9; 2d, 46° 3; 3d, 46° 8; and the departures in defect of their respective aver-

ages were 3° 6, 4° 8, 5° 1, 4° 6, 1° 7, 0° 3, and 1°. The mean temperature of the air for the week was 49° 3, being 3° above the average of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, were 106½° on October 30, and 97° on November 2; on October 29 the reading did not rise above 60°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 27½° on November 3, and 30° on the 2d. The mean of the seven low readings was 35½°.

Wind.—The direction of the wind was S.W., and its strength moderate. The weather during the week was fine and mild, and the sky partially cloudy.

Rain fell on three days during the week, the amount collected was a quarter of an inch.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 62½° at Liverpool, 61½° at Blackheath and Cambridge, and 61° at Truro, Bristol, and Leeds; the highest temperature at Hull was 57°, and at Eccles and Bradford 58½°; the mean value from all stations was 60°. The lowest temperatures of the air observed by night were 33½° at Wolverhampton, 37° at Blackheath, and 37½° at Nottingham; the lowest temperature of the air at Truro was 46°; the general mean from all stations was 40°. The range of temperature in the week was the greatest at Wolverhampton, 25½°, and the least at Truro, 15°; the mean range of temperature in the week from all stations was 20°.

The mean of the seven high day temperatures was the highest at Truro, 59°, and Plymouth, 58°, and the lowest at Hull, 54°, and Wolverhampton, Liverpool, and Bradford, all 54½°; the mean from all stations was 56°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 39½°, and Nottingham, 41½°; and the highest at Truro, 48½°, and Portsmouth and Plymouth, both 46½°; the mean value from all stations was 44°. The mean daily range of temperature in the week was the least at Liverpool, 8½°, and the greatest at Wolverhampton, 15½°; the mean daily range from all stations was 12°.

The mean temperature of the air for the week from all stations was 49½°, being 5° higher than the value for the corresponding week in 1876. The highest were 53° at Truro, 51½° at Plymouth, and 50½° at Portsmouth, Leeds, and Sunderland; and the lowest were 46° at Wolverhampton and 47½° at Hull.

Rain fell on four or five days during the week at most places. The amounts measured ranged from 1½ inch at Bradford and 1 inch at Truro to a quarter of an inch at Blackheath and Sunderland. The average fall over the country was three-quarters of an inch.

The weather during the week was generally fine and mild, but the sky cloudy at times. Solar halos were seen on October 28 and November 3 at Bristol, and a lunar halo was also seen on October 28 at Bristol.

SCOTLAND: Temperature.—The highest temperatures of the air varied from 58° at Dundee and 57½° at Leith, to 54½° at Aberdeen; the mean value from all stations was 56½°. The lowest temperatures of the air ranged from 38° at Dundee to 41½° at Glasgow; the mean value from all stations was 39½°. The mean range of temperature in the week from all stations was 16½°.

The mean temperature of the air for the week from all stations was 48½°, being 3½° higher than the value for the corresponding week in 1876. The highest was 49½° at Glasgow and Leith, and the lowest 46½° at Aberdeen.

Rain.—The amounts of rain measured at the several places varied from 2½ inches at Greenock, and 1 inch at Perth, to four-tenths of an inch at Leith. The average fall over the country was 1 inch.

DUBLIN.—The highest temperature of the air was 63½°, the lowest 35½°, the range 28½°, the mean 50½°, and the fall of rain 0.37 inch.

JAMES GLAISHER.

Law Notes.

A COVENT GARDEN CASE.—This was a representative action to test the custom of the trade, in which the plaintiff, J. Pankhurst, a salesman in Covent Garden Market, sued the defendant, a Mr. W. G. Green, a grower, of Gillingham, Kent, to recover the sum of 16s. for money alleged to have been paid as a deposit on twenty sieves belonging to the defendant. Mr. H. T. Roberts appeared as solicitor for the plaintiff, and Mr. R. Willis for the defence. It appeared from the plaintiff's statement that upon August 15 last he bought twenty sieves of Black Currants and paid £1 as a deposit on the sieves, which were sub-

sequently returned with an application for the deposit, which being refused the present action was brought in order to test the custom of the trade. The witness said the fruit was what is termed in the market "soft," and could not be "shot," and therefore it was necessary to keep the sieves.

James Callum, the plaintiff's porter, was called, who proved receiving the goods and delivering sixteen sieves to the defendant, who refused to give back 16s. until the remaining four were sent back.

In cross-examination, witness said there was no custom in the market as to any specified time for the return of empties.—George Coombes, twenty years a salesman in the market, stated there was no limit as to return of sieves. He had had twelve, eighteen months, and even two years, frequently elapse before he received his own back. There is no custom in the market in this respect.—After three other witnesses had been called in support of the plaintiff's case, Mr. Robert Willis urged on the part of the defence that the goods were ordered to be "shot," and that the sieves were to be returned at once.

The defendant, being called, said that he expected the sieves would have been returned; he had sold 200 sieves that day, and always had his goods "shot."

In cross-examination by Mr. Roberts, the witness said the original cost of the sieves was 1s. 4d. each.

The defendant's son, called, corroborated the plaintiff's evidence, adding that he received payment of the goods and refusing to pay 16s., as the whole of the sieves had not been returned.

The learned Judge considered that the custom of the market had been abundantly proved, that there was no limit to time for the return of empties, and therefore he should give judgment in favour of the plaintiff for the full amount claimed.—On the application of Mr. Taylor Roberts, his Honor granted the plaintiff his costs out of pocket, with costs of five witnesses who had been called.

Variorum.

THE NEW HULL BOTANIC GARDEN.—The first general meeting of the Hull Botanic Garden Company (Limited) was held at the Town Hall on November 3, Lieut.-Colonel Pease in the chair. Mr. Niven (the manager and secretary) read the directors' report, which at the outset stated that only four months had elapsed since the company was registered, consequently the work accomplished had been necessarily of a preliminary kind. The movement of the new garden had received a large amount of support from the residents of Hull and neighbourhood, and already nearly one-half of the shares had been taken up—a fact which augured well for the prospects of the company. Several of the shareholders had intimated their willingness to double the number of their shares in the event of there being any difficulty in getting a larger number taken up—a necessity which, however, they did not apprehend to be at all likely, as many persons, who would willingly give financial support to the scheme, withheld the same till the work was fairly begun. The purchase of the land from the North-Eastern Railway Company had been completed. A deposit of 10 per cent. had been made, and the purchase agreements exchanged. The necessary arrangements had also been completed with Sir James Walker, by which the road on the site of the old Spring-bank was secured. This the directors had found could not be done on any other terms than by purchase. Fairly satisfactory conditions had been obtained, and the directors hereafter might be successful in securing material assistance in the making of the road from other parties interested. So recently had these purchase agreements been completed that the directors had as yet nothing to report beyond the bare fact of their completion, and that in a few days the company would be in possession of the land. Several *bona fide* applications for the building sites connected with the new garden had been made at an amply remunerative price, but they believed that as the works in connection with the laying out of the new garden progressed, the value of those sites would be so much enhanced that they would prefer the company retaining them at present, knowing as they did that a little delay would be more than compensated for by the increased value the sites would acquire. The directors urged on each and all of the shareholders the necessity of an active canvass amongst their friends, as the larger the number of shares taken up the less would be the amount of calls necessary to be paid on each individual share, and the greater the support for the garden. The report was adopted unanimously. After a vote of thanks to the directors for the time and application they had devoted to the affairs of the company, the following gentlemen were appointed directors for the ensuing

year, in accordance with the articles of the company, viz. :—Messrs. J. W. Pease, J. E. Wade, R. Baxter, A. Wilson, Charles Johnson, S. Walliker, T. L. Read, S. R. Meggitt, William Denison, and James Reckitt. Messrs. Carll and Birkenshaw were also appointed as auditors. The meeting then resolved itself into an extraordinary general meeting, and, upon the motion of Mr. Baxter, it was resolved—“That the articles of association of the company now produced, and signed by Messrs. Read, Baxter, Frankish, Walliker, Hamilton, Johnson, and Dawber, be and are hereby adopted, and declared to be the articles of association of the Hull Botanic Garden Company (Limited).”

ROOTERIES.—As a rule I am not a great admirer of rooteries, but there are conditions in which they may be used with advantage, and, like the skeleton, their beauty will much depend on the taste and judgment exercised in placing appropriate materials at Nature's command wherewith to clothe them. The materials provided, the rest should be left to Nature; and amongst these materials none will be found more appropriate than this species of Saponaria (ocymoides). One essential point is that the position should be tolerably well exposed to the sun. Associated with it, I might suggest some of our lovely Clematises, now a numerous family, all of which thrive best when allowed to ramble in natural disorder; a few of the wild Foxgloves, or, better still, some of the more improved garden forms interspersed, will add not only floral beauty to such a group, but give it a picturesque character, such as a few towering Lombardy Poplars or lofty Pines give to the landscape. To complete the picture, let the grass-line rising towards the base of the roots be crowned on its irregular undulating surface with a combination of the wild Bugles (Ajuga reptans), or, better still, its alpine form, whose flowers are of a blue almost rivalling cobalt; and the Lysimachia nemorum, or “Wood Money-wort,” whose simple yellow flowers and fresh green foliage would add a beauty to such a group such as could be obtained from few exotics. A plant or two of common wild Honeysuckle would add its fragrance as well as its beauty to the scene. With such garniture, the rootery, too often an eye-sore, would be metamorphosed into a “thing of beauty and a joy for ever.” J. C. Niven, in “Florist and Pomologist.”

Answers to Correspondents.

FUNGI: G. H., Yeovil. 1, Hygrophorus pratensis; edible; 2, H. puniceus, qualities unknown; 3, H. virgineus, edible.

MOSSY SWEET WILLIAM: G. C. The specimen you send is an excellent example of what the French call by the above name. The true flower is not formed, but in its place the bracts are repeated over and over

FIG. 120.—MONSTROUS SWEET WILLIAM.

again, as shown in the accompanying illustration, fig. 120. The very old Wheat-ear Carnation is another case of a similar kind.

GRAPES OR CUT FLOWERS: T. W. S. asks us to tell him “Which of the two is most profitable, 9000 superficial feet of glass for the growing of Grapes, or 9000 superficial feet of glass for the growth of cut flowers for Covent Garden?” T. W. S. holds too exalted ideas as to our capacities.

HOLLIES: T. B. The present is a very good time to transplant Hollies, if done at once and done well. They may also be successfully transplanted in the late spring months if the conditions are favourable.

INSECTS: D. B. We do not find any insects with your specimen. They should be sent in a closed box, or corked quill.

NAMES OF PLANTS: J. D. Tetragonolobus (Lotus) conjugatus, a plant of the Mediterranean region.—Subscriber, Co. Down. The White Beam, Pyrus Aria.—J. Van V. Staehopea Wardii.—Ab initio. Hornbeam, Carpinus Betulus, var. incisa, fruiting, —

H. A. B., Ashfield.—Fraeoa appendiculata.—W. D. F. Sedum Sieboldii and S. Sieboldii variegata, Platyloma rotundifolium.—A. Kiltick. Eonymus europaeus (the Spindle Tree).—A. B. 1, Polypodium phyllitidis; 2, P. crassifolium; 3, P. repens; 4, Menziesia polifolia.—Subscriber. Adiantum hispidulum.—T. S. P. Cystopteris fragilis, var. dentata. ORCHID FLOWERS DYING OFF: J. T. S. The samples sent look as if possibly injured by fumigation; or they may have been damaged by the sun, or by overhead watering, but without knowing all the circumstances, we cannot say whether any of these are the cause of your loss.

ORCHIDS SPOTTING: E. C. The spotting of the Calanthe flowers is from their being kept in too damp, and possibly too cold, an atmosphere, or from being caught by the spray in syringing.

TRANSPLANTING MACHINE: Subscriber. Barron's will be most likely to suit you. There is more than one size. It would be best to consult Mr. Barron himself.

VASE FOR SPRING FLOWERS: J. D. We hear that Mr. Matthews, of Weston-super-Mare, is making the vases in question.

Markets.

COVENT GARDEN, November 8.

The supply of home-grown Apples has somewhat fallen off, and first-rate samples are in demand at improved prices. Best Cobs sell freely, but for indifferent samples there is no demand. James Webber, Wholesale Apple Market.

Table with columns for fruit types (Apples, Grapes, Lemons, etc.) and prices per unit. Includes sub-sections for Fruit and Vegetables.

Table listing various vegetables such as Artichokes, Asparagus, Beans, Carrots, Cauliflowers, Celery, etc., with their respective prices.

Potatos: — Essex Regents, 90s. to 110s.; Kent Regents, 100s. to 140s.; Kent Kidneys, 140s. to 160s.

Table listing cut flowers including Abutilon, Asters, Bouvardias, Calceolarias, etc., with prices per bunch or dozen.

Table listing plants in pots such as Begonias, Bouvardias, Chrysanthemums, Clematis, etc., with prices per pot or dozen.

SEEDS.

LONDON: November 7.—One or two samples of new home-grown red Clover seed have been shown on Mark Lane, but as yet no opinion can be formed as to the result of the crop as a whole. As regards foreign samples the trade doing continues very limited. The inactivity of the present time presents a great contrast to the excitement of last autumn; just now, in fact, there seems hardly any desire either to sell or buy. Holders both in France and America appear not only indifferent about making sales at current rates, but also quite resolved not to further reduce their prices; and the trade here, having been so bitten last year, are disinclined to operate unless at currencies which scarcely allow the possibility of loss. It is, of course, impossible to predict the future of the Clover trade, but perhaps those are most right who think that values have about seen their lowest. Letters from the United States describe the Illinois seed this year as superior to that of Indiana, Ohio, and some of the Eastern States. White Clovers tend upwards: with a disappointing crop in Germany, and light stocks everywhere, holders exhibit increased firmness. There is no change in either Alsike or Trefoil. The prospects of Trifolium for next year are said to be bad. For winter Vetches there is scarcely any inquiry. Canary seed meets with a small sale on former terms. Hemp seed, on account of its scarcity, is again dearer. For Linseed, both English and foreign, buyers are found at Monday's figures. A moderate business has been doing in Mustard and Rape seed. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

Trade at Mark Lane on Monday showed no improvement on that of last week, indeed prices were even weaker in some cases, the importations of produce continuing on a liberal scale. English and foreign Wheat was from 1s. to 2s. per quarter cheaper than on Monday se night, at which reduction there was little or no better demand. Barley was very quiet, and prices were not altogether so good. Malt was unchanged. Oats were a trifle easier in some instances. Maize was steady on former terms. Beans and Peas were cheaper where pressed for sale. Flour was heavy at a reduction of about 1s. per sack and barrel.—On Wednesday trade was very dull, while every attempt to force sales was accompanied by a further reduction in price. Holders, however, were not over anxious sellers, the statistical position of the trade being opposed to continued depression. The supplies were liberal of foreign Wheat, and moderate of other classes of grain. The condition of the produce was hardly so good, owing to the inclement weather of the last few days.—Averages prices of corn for the week ending November 3:—Wheat, 53s. 8d.; Barley, 42s. 4d.; Oats, 24s. 2d. For the corresponding period last year:—Wheat, 48s. 2d.; Barley, 39s. 4d.; Oats, 25s. 5d.

CATTLE.

At the Metropolitan market on Monday choice English beasts were scarce, and readily made top quotations. Trade was cheerful for all kinds, and a fair clearance was effected. The supply of sheep was short, and prices on the average advanced. A good clearance was effected. Calves, especially choicest qualities, were scarce, and prices better. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 6d. to 6s.; calves, 4s. 8d. to 6s. 2d.; sheep, 5s. 4d. to 6s., and 6s. 4d. to 7s.; pigs, 4s. to 5s.—On Thursday trade was generally quiet. Choice beasts sold at full prices, otherwise quotations ruled somewhat irregular. As regards sheep, there was a fair inquiry for choice breeds at the full prices of Monday. Other qualities sold rather slowly. Calves and pigs were much the same in value.

HAY.

The Whitechapel report for Tuesday states that the demand for fodder was slow, and prices, although unaltered, were hardly so good as on the previous market day. Prime old clover, 100s. to 134s.; inferior, 85s. to 95s.; good new clover, 100s. to 130s.; prime meadow hay, 90s. to 107s.; inferior, 75s. to 85s.; and straw, 44s. to 53s. per load.—There was a moderate supply of fodder at Thursday's market, with a good trade. Prices were firm.—Cumberland Market quotations:—Superior meadow hay, 98s. to 110s.; inferior, 80s. to 90s.; superior Clover, 126s. to 135s.; inferior, 95s. to 110s.; and straw, 52s. to 57s. per load.

POTATOS.

The Borough and Spitalfields markets reports state that sound Potatos continue in moderate request, while there is a dull trade for inferior kinds. The arrivals are liberal of all sorts. Kent Regents, 140s. to 160s.; Essex idiot, 120s. to 150s.; Rocks, 100s. to 120s.; Victorias, 140s. to 170s.; and Kidneys, 120s. to 170s. per cwt.—The imports into London last week included 58,485 bags from Hamburg, 5535 Stettin, 4196 Antwerp, 1482 Dunkirk, 868 Boulogne, 783 bags 151 casks and 36 sacks Rotterdam, 518 bags Harlingen, 3000 bags Danzig, 150 tons Brussels, 541 casks 137 bags Rouen, 10 sacks Amsterdam, and 13 Casks.

COALS.

There was a large supply of house coals on offer at Monday's market, and the prices of last week were current. On Wednesday house coals were steady at Monday's figures, but Hartleys gave way 1s. per ton. Quotations:—Bowers West Hartley, 16s. 3d.; Beside West Hartley, 16s. 3d.; Hastings Hartley, 16s. 3d.; Walls End—Hawthorns, 17s. 9d.; Lambton, 19s. 6d.; Original Hartlepole, 20s.; Newbottle, 17s.; South Hartley, 20s.; Tunstall, 17s. 9d.; Vanes, 17s. 9d.; East Hartlepole, 19s. 9d.; Tees, 19s. 9d.; Thorpe, 17s.

 Mills, Shad Thames, London, S.E.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOUROUS POWDER.

Price, £12 per Ton; 15s. per Cwt; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to
AMIES' CHEMICAL MANURE CO. (LIMITED),
 79, MARK LANE, LONDON, E.C.

GISHURST COMPOUND.

Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outlived many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

SIMPSON'S RED SPIDER, THIRPS, &c., ANTIDOTE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d. Supplied to Seedsmen and Chemists. Strongly recommended in the *Gardener*, and by many first-class Gardeners. Prepared by JOHN KILNER, Wortley, near Sheffield.

Tufa Rock.

MESSRS. H. BUXTON AND CO.,
 Matlock, have much pleasure in offering their TUFFA, a light porous natural Stone, admirably adapted for the construction of Grottos, Ferneries, Aquariums, and General Garden Ornamentation. For terms and particulars apply to our Agent, Mr. H. CHADNEY, 12, Royal Exchange, London, E.C.

Perforated Crocus Vase.

JOHN MATTHEWS, Royal Pottery,
 Weston-super-Mare, begs to intimate that he can supply VASES similar to the one illustrated at p. 537 of the *Gardener's Chronicle* for October 27.

Rosher's Garden Edging Tiles.

THE ABOVE and many other PATTERNS are made in materials of great durability. The plainer sorts are specially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "growa" Edgings, consequently being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design. F. ROSHER AND CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E.

Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.

Illustrated Price Lists free by Post. The Trade supplied.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable Paving of great durability, Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety, Slates, Cement, &c. F. ROSHER AND CO., Brick and Tile Merchants. See addresses above.

SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post. FLINTS and BRICK BURS for Rockeries or Ferneries. KENT PEATS or LOAM supplied at lowest rates in any quantities.

F. ROSHER AND CO.—Addresses see above.
 N.B.—Orders promptly executed by Rail or to Wharves. A liberal Discount to the Trade.

SIR J. PAXTON'S HOTHOUSES for the MILLION.—Price List free. Conservatories, &c., built to Architects' Plans, or Designs prepared and Estimates given to Rough Sketches, with sizes required. Heating apparatus fixed complete. Pamphlet, with Illustrations, post-free, 3d. HEREMAN AND MORTON, 2, Gloucester Street, Regent's Park, London, N.W.

RICHARDSON'S PATENT HORTICULTURAL BUILDINGS

SECTION OF PATENT ROOF VENTILATOR

Illustrations, Price Lists, and Testimonials free. Hot-water Apparatus fixed in any part of the Kingdom, and guaranteed.

W. RICHARDSON & CO., Horticultural Builders & Hot-water Engineers, **DARLINGTON.**

Metallic Hothouse Builder to Her Majesty. **HENRY HOPE** (late Clark & Hope, formerly Clark), HOTHOUSE BUILDER and HOT-WATER APPARATUS ENGINEER. 55, Liool Street, Birmingham. Established A.D. 1818. BOOKS OF DESIGNS, 5s. each. The Extensive Ranges of Metallic Hothouses in the Royal Gardens, Windsor and Osborne, were executed in this Establishment.

FOR SALE, cheap, a first-class GREENHOUSE, 80 feet in length by 20 feet, divided into three sections, one centre, 20 feet, and two ends, 30 feet. **KEEN AND SON,** Church Street, Croydon.

LASCELLES' PATENT BENT WOOD CONSERVATORIES and GREENHOUSES.—All Gardeners know that Wood is better than Iron for Plant Growing, and by the above system a handsome curved house can be erected as cheaply as a plain straight one. The curved house is more durable, stronger, lighter in construction, and of bent glass is required. **W. H. LASCELLES,** 121, Bunhill Row, London, E.C., will supply Drawings and Estimates free of charge.

JOSEPH BRAMHAM, HORTICULTURAL and HOT-WATER ENGINEER, WIRE WORKER, WEAVER, &c., 104, Dale Street, and 44, Elizabeth Street, Liverpool. J. B. strongly recommends the **ALLERTON PRIORY BOILER** as one of the most powerful for extensive work. He has fixed one capable of heating 10,000 feet of 2-inch piping. See *Gardener's Chronicle*, p. 647. Also his **WELDED WROUGHT IRON WATERWAY BACK** for ordinary Saddle Boilers. These Backs can be fixed to any Boiler now in use, and are a great saving in fuel and labour. He is also prepared to fix any kind of Boiler made. Manufacturer of the Registered **LIVER FRONT** for large Boilers, **IRON and WIRE WORK** in all branches. References from Noblemen and Gentlemen for work done. Plans and Estimates given.

CRITCHLEY'S PATENT HEAT REGULATOR, AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves. The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler. The following Testimonial has been received:—

Berkeley Castle, April 13, 1875. "Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes. "I am, Gentlemen, yours truly, "R. H. CRONK, "Gardener to the Right Hon. Lord Fitzhardinge." Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

Messrs. CRITCHLEY & CO., Horticultural Engineers and Builders, **GROSVENOR WORKS, CHELTENHAM.**

THE "ECONOMIC" HOT-WATER APPARATUS,

Comprising **WROUGHT-IRON BOILER, PIPES, CISTERN,** and all necessary Connections and Fittings, complete and ready for erecting.

PRICE:— No. 1 Apparatus (with 72 feet of 2-in. piping), £5 5s. No. 2 Apparatus (with 36 feet of 2-in. piping), £3 10s.

Illustrated Sheets and particulars on application to **HOT-WATER APPARATUS WORKS,** 31, Bankside, London, S.E.

SILVER MEDAL AWARDED AT **Birmingham Meeting, Royal Agricultural Society, 1876.** **HIGHEST HONOR** AT THE **Centennial Exhibition, Philadelphia, 1876.** Specially adapted for Pumping in Gentlemen's Houses and Grounds. No Labor Required. **HAYWARD TYLER & Co.,** 84, WHITECROSS STREET, LONDON.

ART-WITH-ECONOMY-APPLIED-TO-CONSERVATORIES

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches x 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fitting, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts.

T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description. Full-sized specimens of Greenhouses, &c., and Hot-water Apparatus in work, can be inspected at Mansion House Buildings, London, E.C. Gentlemen waited upon at their residences by experienced designers.

Copy of a Testimonial.

"Royal Exotic Nursery, King's Road,
Chelsea, S.W.—Aug. 5, 1877.
"GENTLEMEN.—In reply to your enquiry as to our opinion
of your Stevens' Trentham Boilers, we do not hesitate to pro-
nounce them to be *by far the best* Boilers we have ever used.
Our establishment is a very large one, and we have tested most
of the various descriptions of Boilers which have been brought
out from time to time. We originally commenced with *one* Tren-
tham Boiler, and we have now *thirteen* of various sizes at work.
"For certainty of action, economy in fuel, and freedom from
breakdown, we have never had a Boiler at all equal to the
Stevens' Riveted Trentham Boilers supplied by you, and
we have never felt so little anxiety in connection with our hot-
houses during the cold winter months as we do now.
"We are not in the habit of giving testimonials, but we
think this may fairly be an exception to our rule, as the matter is
one of such importance to the Gardening Public generally,
and our experience has led us to form a very decided opinion.
"We are, Gentlemen, yours faithfully,
"JAMES VEITCH AND SONS."

For Illustrations, with full particulars apply to the Sole Makers,
F. & J. SILVESTER.

HOT-WATER ENGINEERS, &c., &c.,
Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction
and under the inspection of the inventor, Mr. Stevens—all
others being base imitations.

 Off-hand or Home Farm.—Age 25, married; has a practical knowledge of Agriculture.—W. FIELD, Shitty Green Farm, Preston, near Hitchin.

KINAHAN'S LL WHISKY.
 Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale to: 20, Great Titchfield Street, London, W.

GRATEFUL—COMFORTING.

JAMES EPPS & CO.,
 HOMEOPATHIC CHEMISTS,
DINNEFORD'S FLUID MAGNESIA.
 The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.
 DINNEFORD AND CO.,
 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S OINTMENT AND PILLS.
 —Colds, Coughs, Shortness of Breath.—These corrective remedies are infallible for these pectoral complaints, which, neglected, often end in asthma, bronchitis, or consumption. The Ointment, well rubbed upon the chest and back, penetrating the skin, is carried directly to the lungs, whence it expels all impurities. All the blood in the body constantly passes through the lungs, and there all noxious particles tending to produce disease can be quickly, thoroughly, and permanently neutralised, rendered harmless, or ejected from the system. Holloway's Ointment and Pills perfectly accomplish this purification, and through the blood, thus cleansed, the influence of these wonderful medicaments reaches the remotest parts of the human body, and thus cures all diseased action, whether internal or external.

Cures of Old Standing Asthma, Colds, &c. by
DR. LOCOCK'S PULMONIC WAFERS.
 —From Mr. ROBINSON, *Chemist, Trinity Street, Hull*:—"In all affections of the Chest, old-standing Asthma, and neglected colds they seem to act like a charm." In Consumption, Bronchitis, Coughs, and Rheumatism, they give instant relief and taste pleasantly. Sold at 1s. 1½d., 2s. 6d., 4s. 6d., and 11s. per Box by all Druggists

Sole English Medallists for the Best Hot-Water Apparatus at the United States International Centennial Exhibition, Philadelphia.

WRIGHT'S ENDLESS-FLAME-IMPACT HOT-WATER BOILERS.

"The 'Boiler of the Future.' I have no doubt about this."—WM. THOMSON, *Clovenfords.*

We can supply Foundation Plates—which form Ash-pit—and Smokestacks, if wanted, thereby doing away with the necessity for even a single brick in their erection.

	A	B	C	D	E
Foundation Plate ..	s. d.	s. d.	s. d.	s. d.	s. d.
Smokestack, Damper, and Soot-Door ..	35 0	45 0	60 0	75 0	90 0
Furnace and Ash-Pit, Frame and Doors; also Furnace Bars, Bearers, Dumb-Plate, &c. ..	30 0	40 0	50 0	60 0	70 0

Foundation Plates are arranged to heat the air before it is sent into the ash-pit at back, and furnace-doors to heat the air before its admission into the furnace, furnishing in fact two "hot-air" blasts to the furnace; the admission of large volumes of cold air being most injurious to the economical working of the furnace.

In preparation an entirely NEW SERIES of SEVENTY BOILERS, embracing a large variety suitable for small places, &c., and all specially adapted for low situations where shallow boilers are a necessity. Particulars on application.

WM. WRIGHT & CO.,
AIRDRIE, N.B.

SALES BY AUCTION.

Dutch Bulbs.

MR. J. C. STEVENS will **SELL** by AUCTION at his Great Rooms, 38, King Street, Covent Garden, W.C., every MONDAY, WEDNESDAY, and SATURDAY during November, consignments of Double and Single HYACINTHS, TULIPS, for glasses, pots, and borders; CROCUSES, of all colours; NARCISSUS, ANEMONES, SNOWDROPS, GLADIOLI, LILIIUMS, and other BULBS arriving weekly from well-known farms in Holland, in large and small lots to suit all buyers.

On view the morning of Sale, and Catalogues had.

N.B.—The Sales each day commence at half-past 12 o'clock precisely, and generally finish about half-past 5 o'clock.

Hardy Plants and Bulbs.

MR. J. C. STEVENS will **SELL** by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on WEDNESDAY, November 21, at half-past 12 o'clock precisely, 1000 Choice Standard and Dwarf ROSES from the English Nursery, also from Holland splendid specimen variegated Green HOLLIES, Rare CONIFERS, FRUIT TREES, &c., from a well-known Dutch Nursery. Also a great variety of DUTCH BULBS, &c.

On view the morning of Sale, and Catalogues had.

Rare Dendrobiums from New South Wales.

MR. J. C. STEVENS will **SELL** by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, November 22, at half-past 12 o'clock precisely, 150 Plants of the rare DENDROBIUM JOHANNIS, several of them very fine, with from ten to sixteen stems; and about 400 Plants of DENDROBIUM BIGIBBUM, many of them splendid strong plants, with from ten to fifteen stems; among these will probably be found several varieties, and doubtless the beautiful D. BIGIBBUM SUPERBUM, for some of the plants have stout, strong stems, upwards of 4 feet in length.

On view the morning of Sale, and Catalogues had.

Imported Orchids.

MR. J. C. STEVENS will **SELL** by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, November 22, at half-past 12 o'clock precisely, an importation, in extra fine condition, of ONCIDIUM KRAMERIANUM, ODONTOGLOSSUM ROEHLII, ONCIDIUM UNGUICULATUM (Lindley), twenty-five large masses of the pure white MAXILLARIA GRANDIFLORA (Reich.), and a quantity of COOL ORCHIDS, by order of Messrs. F. Sander & Co., St. Albans.

On view the morning of Sale, and Catalogues had.

Lapageria alba.

MR. J. C. STEVENS will include in his SALE on THURSDAY, November 29, Thirty-six Plants of various sizes of the beautiful LAPAGERIA ALBA, some of which are in flower, the property of Mr. Howard, Florist, 29, King Street, Covent Garden, W.C.

Auction Rooms and Offices, 38, King Street, Covent Garden, W.C.

Dendrobium bigibbum superbum.

MR. J. C. STEVENS will **SELL** by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, November 29, at half-past 12 o'clock precisely, a splendid consignment of DENDROBIUM BIGIBBUM SUPERBUM, by order of Mr. B. S. Williams, who has much pleasure in offering this hitherto rare and expensive Dendrobium, received from his collector in Torres Straits. It will be seen from the Plants in flower that there is no question about its being the true variety, producing, as it does, bulbs averaging from 12 to 24 inches in length, and flower-spikes producing as many as ten highly-coloured flowers. All the plants here offered are starting freely into growth, and many of them are throwing up spikes from the old bulbs, which it is expected will attain maturity, as some of the plants exhibited in flower are from the same importation. At the same time will be offered sixty fine imported trunks of TODIA SUBERBA, a collection of STOVE and GREENHOUSE PLANTS, &c.

On view the morning of Sale, and Catalogues had.

Unreserved Sale of a Large Consignment of Selected HYACINTHS for Pots, Glasses, or Borders, fine named CROCUS and TULIPS, also POLYANTHUS, NARCISSUS, and other BULBS, choice LILIES, ANEMONES, and other BULBS from Holland, together with about 400 English-grown ACHIMENE BULBS.

MESSRS. PROTHEROE AND MORRIS will **SELL** the above by AUCTION, at the Auction Mart, Tokenhouse Yard, E.C., near the Bank, London, on MONDAY NEXT, half-past 11 o'clock punctually.

Catalogues had of the Auctioneers, 98, Gracechurch Street, London, E.C., and Leytonstone, E.

Norwood Road, S.E.

(Near Tulse Hill Station.)

W. WISEMAN AND SON have a very large quantity of the above to Dispose of, cheap. Prices on application.

Black Friars and Grove Terrace Nurseries, Elgin, N.B.

Gold, Silver and Green Hollies.

J. J. MARRIOTT has a choice assortment of Hollies, in various sizes, and begs to offer them in Collections of Twenty distinct kinds, including Perry's Silver Variegated Weeping, at 25s. to 45s. each, according to size of plants.

Mellish Road, Walsall.

WM. KNIGHT, Floral Nursery, Hailsham, Sussex, intimates that his New General CATALOGUE of NURSERY STOCK, of fifty pages, will be forwarded on application for three stamps, free to Purchasers, consisting of one of the best grown stocks in Europe.

Specialties—Roses, Fruit Trees, and Rhododendrons.

First-class Nursery Stock.

WITTY AND SON have to offer dwarf-trained PEACHES and NECTARINES. Also pyramid and standard APPLES, PEARS, PLUMS, and CHERRIES. An immense stock of EVERGREEN SHRUBS of first-class quality.

The Nurseries, Cottingham, near Hull.

CHEAP OFFER.—Ozothamnus rosmarinifolius, white, useful for cut flowers; Escalloia macrantha, very fine for potting; Cotonaster microphylla; Pyracantha, red-berried; Aristotelia Maqui, fine evergreen, with Laurel-like foliage, seldom offered; Santoinia chamacyparissus, white foliaged evergreen; Loniceria aurea reticulata, Sambucus aurea variegata, admirable for town gardens; Ribes sanguinea. All the above at 2s. per dozen, 45s. per 100. Laurustinus, common, shining and black-leaved, 7s. 6d. per 100, 60s. per 1000.

WILLIAM ABRAHAM, Nurseryman, Limerick.

B. WHITHAM, The Nurseries, Reddish, near Stockport, has for Sale:—

50,000 ENGLISH YEWS, extra fine, many times transplanted, 1 to 2 feet, 20s. per 100; 2 to 3 feet, 40s. per 100; 3 to 4 feet, 60s. per 100. Great reduction to purchasers of 1000 and upwards.

Also to be sold cheap many Thousands of HORSE CHESTNUTS and LIMES, 8 to 10 feet, fine for avenues.

To the Trade.

SEEDLING TREES.—2,000,000, consisting of 1-yr. Larch, 1-yr. Alder, 1-yr. Scotch Fir, 1-yr. Thorn Quick, 1-yr. Sycamore, all grown from home-saved native Irish seed. Samples and Prices on application to Mr. WILLIAM ALLEN, Dangan, Summerhill, Enfield, Co. Meath, Ireland.

TUBEROUS BEGONIA SEED.—Saved from our unrivalled collection, fresh harvested, and only a very small quantity to offer. In sealed packets at 2s. 6d. and 5s. each.

RODGER McCLELLAND AND CO., Nurseries, Warrenpoint Road, Newry.

P.S.—Our NEW CATALOGUE of New and Old Varieties will shortly be issued, and will be sent on application.

CUPRESSUS LAWSONIANA DENSA. RETINOSPORA PLUMOSA AUREA.

The above CONIFERS are singularly beautiful; the Cupressus having a rich dark glaucous green foliage, and the Retinospora a perpetual bright golden-yellow. They are of very compact growth, perfectly hardy, and admirably adapted for lawns, water bedding, and small window balconies. Nice specimens are offered singly or in any quantity.

1 foot, 2s. 6d.; 1½ foot, 3s. 6d.; and 2 feet, 5s. each.

W. H. ROGERS, Red Lodge Nursery, Southampton.

Cabbage Plants, Cabbage Plants.

W. VIRGO AND SON can now supply in any quantity good strong, healthy plants, viz., Early Battersea, Early Enfield Market, Early Noopariel, and Sugar-loaf Cabbages, all at 3s. per 1000; Robinson's Drumhead, 3s. per 1000; Red Drumhead, 5s. per 1000; delivered free on rail. Post-office Orders must accompany all orders from unknown correspondents. W. VIRGO AND SON, Womersley Nursery, near Guildford.

KENTISH FRUIT TREES.—One of the largest and cheapest stocks in the county, consisting of tall Standard CHERRIES, Standard, Pyramid, and Espalier APPLES, PEARS, and PLUMS, from 70s. per 100; GOOSE-BERRIES, CURRANTS, &c.

CATALOGUES of 300 varieties, including all the heavy and sure croppers suitable for Market Growers. Established 1810. T. EVES, Gravesend Nurseries.

NEW HARDY RHODODENDRONS.—MRS. MENDEL, SIGISMUND RUCKER, MARCHIONESS OF LANSOWNE.

The above beautiful and distinct hardy Rhododendrons will be supplied for Three Guineas. ANTHONY WATERER, Knap Hill, Woking, Surrey.

MYROBALAN, or CHERRY PLUM, is the best stuff for Mending Old Fences or Making New Ones. It grows vigorously in the poorest soils, even where White-thorn will hardly exist, and bears clipping like White-thorn. Its stiff hard branches, and dangerous spines or thorns, effectually prevent cattle or evil-disposed persons from getting through Fences made of it. Plant from four to six in a yard. Sizes and prices on application. EWING AND COMPANY, The Royal Norfolk Nurseries, Eaton, near Norwich.

Cabbage Plants, Cabbage Plants.

S. BIDE can supply, for Cash, good strong plants of Enfield Market, Imperial, Improved Non-pareil, and Drumhead or Cattle CABBAGE, at 3s. per 1000, free on rail and package fee; and or Pickling CABBAGE, 5s. per 1000. All the above are grown on light land, and are beautifully rooted. Send orders early to S. BIDE, Alma Nursery, Farnham, Surrey.

Fruit Trees, Deciduous and Evergreen Shrubs, CONIFERÆ, &c.

CHARLES TURNER'S New CATALOGUE of the above is now ready, and can be had post-free on application. The Royal Nurseries, Slough.

GIANT LILY OF THE VALLEY.—Strong blooming Roots, 2s. per dozen, 12s. 6d. per 100, package free.

ROSES, Dwarf, the "Mile Ash dozen," twelve best varieties, extra strong plants, for 6s. 6d. package free. EDWIN COOLING, Mile Ash Nurseries, Derby.

Special Offer.

SEEDLING MEZEERONS, HOLLIES, RHODODENDRONS, and LOMBARDY POPLARS.—1-yr. Seedling Mezeerons, 20s. per 1000; 2-yr. ditto, 30s. per 1000. Common Green Hollies, 1 to 1½ foot, 15s. per 100; ditto, 2 feet, 30s. to 40s. per 100—grown on heavy clayed land, and well rooted. Rhododendrons, Cunningham's White, 1 foot, 9s. per dozen; ditto, 2 to 2½ feet by 2 feet, 30s. to 35s. per dozen; caucasicum pictum, 2 to 3 feet, 30s. to 35s. per dozen—full of bloom-buds, for forcing, bushy plants. Lombardy Poplars, 6 to 8 feet, 10s. per 100; ditto, strong, 10 to 12 feet, 10s. per dozen. New Musk, Harrisoni, 4s. per dozen. Also other Nursery Stock. Samples on application.—PETER LEIGH, Nurseryman, Scholeses Nurseries, Elton, near Dury, Lancashire.

Queen of Lilies, Lilium auratum.

As this year's shipments will be shortly arriving from Japan, WILLIAM GORDON begs to call attention to the following low prices—SIZES: No. 1, 6d.; No. 2, 1s.; No. 3, 1s. 6d.; No. 4, 2s. each. Sampling orders are supplied only in the following quantities, and are carefully packed in tin boxes to contain only the following number of bulbs, the prices quoted including carriage to any part of the United Kingdom:—2 bulbs, 6d. extra; 4 bulbs, 1s. 6d.; 8 bulbs, 2s.; 12 bulbs, 2s. 6d., added to the foregoing prices. Quantities of 18 bulbs and over package and carriage free, less 10 per cent. discount. WILLIAM GORDON, Lily, Bulb, and Plant Importer, 10, Cullum Street, London, E.C.

SPRING FLOWERING PLANTS.

ANEMONE FULGENS, strong plants, established in pots, 12, each, 10s. per dozen, 75s. per 100. This is the most dazzling scarlet, and commences to open its flowers in January and continues until May. Most invaluable for the spring garden, and also for cutting, as it opens its flowers just as well under artificial as real light.

CARDAMINE PRATENSIS, fl. pl., Double Lilac, flowers most profuse, first-rate spring flower, 25s. per 100. PRIMROSE, Double Crimson (true), 18s. per dozen, 140s. per 100.

" Double Crimson Purple, fine variety, often throwing up its flowers in scapes, and continuing long in bloom, 6s. per dozen, 45s. per 100.

" Double Yellow, 4s. per dozen, 25s. per 100.

" Double Lilac, 3s. per dozen, 16s. per 100.

" Double White, 3s. per dozen, 20s. per 100.

" Single Yellow, flowering in scapes, most continuous, 6s. per dozen, 40s. per 100.

POLYANTHUS, strong fine strain, 3s. per dozen, 12s. 6d. per 100.

PHLOX, verna, 4s. per dozen, 20s. per 100. setacea, 4s. per dozen, 20s. per 100.

WALLFLOWERS, Single, Harbinger, Tom Thumbl, yellow and early dark brown, 1s. 6d. per dozen, 8s. per 100.

" Double Germans, eight distinct colours, separate, very strong, 1s. 6d. per dozen, 8s. per 100.

" Double Golden Bred (gold), 3s. 6d. per doz., 25s. per 100.

" Double, black and striped (pots), 4s. per dozen. DAISY, Double Crown, very large, 3s. 6d. per 100.

" Snowball, fine, 3s. 6d. per 100.

" Crimson, 5s. per 100.

" Aucubifolia, 10s. per 100.

" Small White French and Carmine French, two very pretty sorts, 7s. 6d. per 100.

" Cerulea (Blue) Bred, 4s. per dozen.

IRIS, pumila, 3s. per dozen.

MYOSOTIS, rupicola (pots), grows 3 inches high; a gem, 6s. per dozen.

RODGER McCLELLAND AND CO., Nurserymen, &c., Newry.

Florists' Flowers, and Roses.

Autumn Edition.

THOMAS S. WARE has pleasure in announcing that the above new CATALOGUE is now ready; it includes Winter-Flowering Carnations and Pinks, Fancy, Self and Show Plants, Daisies, Pansies, Pzonies, Phloxes, Violas, Violets, &c. Free on application. Hale Farm Nurseries, Tottenham, London.

To the Trade.

MESSRS. LEVAVASSEUR AND SON, NURSERYMEN, Usny, Calvados, France, have an immense stock of Seedling FOREST TREES, Hardy, Coniferous, and other SHRUBS, for transplanting and transplanted; several millions of 1-year THORN. Priced CATALOGUES may be had of Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C.

Tree Ferns, Tree Ferns, Tree Ferns.

DICKSONIA ANTARCTICA.—The Advertiser continues to offer the above at greatly reduced prices. All trunks carefully selected by an English gardener from the coolest districts of Tasmania, from 1 foot upwards. They are carefully dressed and packed, and put on double ships sailing direct to London. Special terms to large buyers: For particulars apply to Mr. WALKER, 9, Mount Pleasant, Tunbridge Wells.

FINE STANDARD ORNAMENTAL TREES, &c., for Immediate Effect.

ASH, Mountain, 8 to 10 feet, fine, 10s. to 12s. per dozen. BEECH, Green, 10 to 12 feet, fine, 18s. to 24s. per dozen. BIRCH, Silver Weeping, 12 to 15 feet, fine, 18s. to 24s. p. doz. CHESTNUT, Horse, 8 to 10 feet, fine, 10s. to 12s. per dozen. " Scarlet, 8 to 10 feet, fine, 12s. to 15s. per dozen. ELMS, Giant Canadian, 15 to 20 feet, fine, 25s. to 30s. per doz. " Lombardy, 10 to 12 feet, fine, 9s. to 12s. per dozen. PRIVET, Evergreen, 3 to 3½ feet, fine, 14s. per 1000. SYCAMORE, 15 to 20 feet, fine, 18s. to 25s. per dozen. Descriptive CATALOGUE of General Nursery Stock post-free on application. W. BALL AND CO., The Nurseries, Bedford Road, Northampton.

Orchard Planting, &c.

H. F. SMITH AND SONS, SEED MERCHANTS, Selby, being about to give up their Nurseries, will offer the whole of their splendid stock of FRUIT TREES, &c., at about half the usual price. It comprises about 10,000 Apples, Pears, and Plums; 10,000 Gooseberries, of best sorts; 5000 Black Naples Currants; 5000 Northumberland Filibasket Raspas (extra strong canes), &c., as well as fine stocks of FOREST and ORNAMENTAL TREES, SHRUBS, CONIFERS, &c., all clean and healthy. A dozen or 100 sent as sample if required.

Vines—Vines—Vines.

B. S. WILLIAMS begs to announce that his VINES this year are in unusually fine condition, and are now ready for distribution.

NEW LATE-KEEPING BLACK GRAPE, "ALNWK SCHEIDING."—This Grape was exhibited before the Fruit Committee, South Kensington, February 6, 1876, under the name of Clive House Seedling, a name the Committee have since thought fit to alter. The following is the description given by the Fruit Committee:—"It is a seedling between the Black Morocco and an unnamed variety raised at Wortley. The bunch shown was of fair size and well shouldered, and the berries large, oval in form, and jet black in colour, with a thick skin. The flavour was decidedly good, partaking of the rich sparkling flavour of the Black Morocco, but much sweeter. It has kept well till February, and will, no doubt, keep longer and prove a better Grape for general cultivation than the Black Alicante." This has been awarded a First-class Certificate. The stock offered is from the original plant. Early orders are respectfully solicited, as the stock is limited. Price 2s. and 4s. each. For Detailed List see BULB CATALOGUE.

NEW FIG, "HARDY PROLIFIC."—The fruit of this hardy Fig is about the medium size, Pear-shaped, rather tapering towards the stalk. The flesh is very sweet and luscious. It was introduced from France some few years ago, and has proved itself perfectly hardy. It must become a general favourite, as it is a very abundant bearer, either in pots or in a cold house, as well as on an open wall. It also ripens earlier than any other variety we know of. Price 10s. 6d. each. Extra sized fruiting plants, 2s. each.

B. S. WILLIAMS, Victoria and Paradise Nurseries, Upper Holloway, London, N.

To the Trade.

MAGNOLIA GRANDIFLORA (Exmouth).—Splendid plants from open ground, 2 to 3 and 4 feet, 18s., 24s., and 30s. per dozen; fine, in pots, 24s. and 30s. per dozen.

A large and excellent stock to select from. WALTER CHARLES SLOCOCK (late Robert Donald & Son), Goldworth Old Nursery, Woking, Surrey.

RHODODENDRONS of the finest named varieties of Hardy Scarlet, White, Rose, and others, in variety. Healthy bushy plants, 1½ to 2 feet, £5 5s. per 100; 2 to 3 feet, £7 7s. per 100; selected, covered with bloom-buds, 18s., 24s., and 30s. per dozen.

HYBRID SEEDLING RHODODENDRONS, raised from the best named kinds, and may be relied on to produce a variety of colour, many equal to named varieties. Good stuff, 1 to 1½ foot, 3s. per 100; 1½ to 2 feet, 5s. per 100; 2 to 3 feet, 7s. 5s. per 100; well set with bloom-buds, 50s. to 100s. per 100.

PONTICUM RHODODENDRON, 1 foot, luscious, 15s. per 100; 1½ to 2 feet, luscious, 20s. and 30s. per 100; 2 to 3 feet, luscious, 40s. to 50s. per 100.

WALTER CHARLES SLOCOCK (late Robert Donald & Son), Goldworth Old Nursery, Woking, Surrey.

CLEMATIS.—Strong plants, in leading kinds, 75s. per 100.

AMPELOPIS VEITCHII, 10s. per 100.

VAREGATED VINES, of best sorts, strong, 75s. per 100.

TRADE LIST of General Nursery Stock on application.

WALTER CHARLES SLOCOCK (late Robert Donald & Son), Goldworth Old Nursery, near the Woking Station, Surrey.

WALLFLOWERS, finest dark, 2s. 6d. per 100.

All the above cheaper by the 1000. Orders amounting to 20s. boxes and packing free.

The Nurseries, Bedford Road, Northampton.

Vines and Strawberries.

" Plant now to ensure a full crop of fruit next season."

FRANCIS R. KINGHORN begs to announce that his stock of VINES, including all the leading varieties, is very extensive, and in excellent condition this season. The Canes are very fine, well ripened, and perfectly free from disease. Strong Planting Canes, 3s. 6d. to 5s. each; strong Fruiting ditto, 7s. 6d. to 10s. 6d. each. Also his collection of STRAWBERRIES includes all the most popular kinds, and are ready for immediate planting. Price, in small pots, 16s. to 20s. per 100; from the open ground, 3s. to 5s. per 100.

Less numbers than 100 of any variety can be had, if desired. Prices to the Trade and LISTS post-free, on application. Sheen Nursery, Richmond, Surrey.

Glad!oli!—New Roses!—Glad!oli!

EUGENE VERDIER, Horticulturist, 37, Rue Clisson, Gare d'Ivry, Paris.

New varieties of ROSES obtained in this Establishment, and to be offered for sale for the first time in November:—HYBRID PERPETUAL S. Charles Baltet, Charles Duval, Comtesse de Flanders, Docteur Auguste Krell, Mdme. Albani, Mdme. Maria Castel, Mdme. Maria Verdier, President Schlachter, Princesse Blanche d'Orleans, Souvenir d'Argenteau Riviere.

New varieties of GLADIOLI to be offered for sale for the first time in November:—Caprice, Conquête, Ciguis, Eglice, Eugene Ramey, Lactea, La France, La Perle, Leviathan, Madamam Platz, Parmentier, Pasquin, Séduction, Tour du Monde.

New varieties already on sale, magnificent, very recommendable, and much recommended:—Madame Krelage, Lord Hawke, Madame de Cazes, Roi des Jaunes, &c.

CATALOGUES are now ready, and will be sent gratis, on demand, post-paid.

THE NURSERIES, Wandsworth Common, Garratt Lane, and Tooting.

The Nurseries comprise 70 Acres of a remarkably useful and well grown stock of HARDY SHRUBS, FRUIT, FOREST, and ORNAMENTAL TREES, CLIMBING PLANTS, &c., especially adapted for planting near London. A personal inspection earnestly solicited. Catalogues free on application to R. AND G. NEAL, Chief Offices, Wandsworth Common.

The Nurseries are situated one mile from Clapham Junction, on the highroad from Wandsworth to Tooting, and a quarter of a mile from Wandsworth Common Station, Loddoo, Brighton, and South Coast Railway.

HOTEIA (SPIRÆA) JAPONICA.—100,000, in very strong and sound condition.

SPIRÆA JAPONICA, 16s. to 20s. per 100; have been awarded several First Prizes, and always considered best shown.

DIELYTRA SPECIABILIS, very strong, 20s. to 26s. per 100.

LILIUM LANCI-FOLIUM ALBUM MONSTROSUM, 30s. to 40s. per 100; very free flowering.

" ROSEUM, strong, 20s. to 26s. per 100.

" RUBRUM, strong, 20s. to 26s. per 100.

" CHINENSIS TIGRINUM, 3s. to 7s. per 100

Trade Catalogues on application. Post-office Order or good reference from unknown correspondents.

BUDDENBORG BROS., Nurserymen, Hillegom, near Haarlem, Holland.

The Greenest Nurseries.

ROBERT F. DARBY begs to offer the following TREES for immediate effect, all straight, handsome, well-rooted, and cheap; price, according to quantity, on application:—

ELM, Chichester, 16 to 20 feet.

HORNBEAM, 5 to 6 feet.

BEECH, 6 to 8 feet.

LIMES, 10 to 12 feet.

NORWAY MAPLES, 10 to 12 feet.

SYCAMORES, 12 to 16 feet.

Also dwarf Bush APPLES, of best sorts, in good bearing, an excellent lot for Market Gardeners.

The Best Hardy Bedding Plant.

CLEMATIS JACKMANNI.—Flowers rich purple, 4 inches across, and so profuse as to completely cover the bed. Begins to bloom in June, and continues until severe frost. It is perfectly hardy, and the stools improve annually. The only secret of success is a rich soil, to keep up free growth. Strong plants in pots, 12s. per dozen; extra strong plants, 2 years old, 18s. per dozen. Other sorts of Clematis and Climbers in great variety. Descriptive LIST on application.

RICHARD SMITH, Nurseryman, Worcester.

A B C Descriptive Bulb Guide.

THOMAS S. WARE has pleasure in announcing that the above for the present season is now ready, containing complete Lists of Lilliums, Narcissus, &c.; also a selection of Terrestrial Orchids, Bamboos and Ornamental Grasses, Climbing Plants and Herbs; to which is added an abridged List of Hardy Perennials adapted for autumn planting. Post-free on application. Hale Farm Nurseries, Tottenham, London.

HYDRANGEA PANICULATA GRANDIFLORA.—We can offer extra strong, bushy plants of this really fine, hardy shrub, 2 to 3 feet high, at 18s. and 24s. per dozen. It should be known that this is quite deciduous, and (unlike the commonly known Hydrangeas, which only bloom on the tops of the ripened shoots of the preceding year), flowers on the young shoots of the current one, and so is sure to flower where the others do not.

STOTT'S MONARCH RHUBARB.—The stems grow to an enormous size, and are of a fine Gooseberry flavour.

From the *Canadian "Weekly Globe"*—"Shirley Hibberd says that any one who wants a Rhubarb that makes leaves as big as a dining table, or stems as thick as a Cedar Tree, that rise as high as a tall human dwarf, should order Stott's Monarch at once. After being at sea for three years as to the whereabouts of this wonderful Rhubarb, he has at last discovered that it is obtained from Stuart & Mein, Kelso."

Roots 1s. 6d. each.
STUART, MEIN AND ALLAN, Nurserymen and Seedsmen, Kelso.

HARDY CLIMBERS,

ROSES, &c.,

Is now ready, and will be sent free on application.

The Nurseries, Huntingdon.

BEAUTY OF HEBRON POTATO.—This new American sort is now offered for the first time. This valuable Potato originated in 1874 from seed bulbs of the Chili Red. The vines and leaves strongly resemble those of the Early Rose, only more vigorous. The plants appear above-ground very shortly after planting, and from that time continue to grow with great rapidity, outstripping all other varieties in strength and luxuriance of foliage. On this account it will be understood they withstand better the ravages of the Colorado Potato Beetle than any other Potato yet brought before the public. The tubers, shaped like those of the Early Rose, are very smooth, slightly tinged with pink around the eyes, but attain a pure white colour during the winter. Their yield is really enormous. The tubers lying closely together in the hills, the labour of digging them is but slight. In point of earliness it may be ranked as ripening at least twelve days earlier than the Snowflake, and no less than three or four days ahead of the Early Rose. For culinary purposes its mealy qualities and richness and delicacy of flavour give it a precedence before all other varieties. Contrary to what is usually the case in all large specimens of Potatoes the Beauty of Hebron almost invariably prove sound and solid to the core. May be obtained of the principal Seedsmen of England.

J. M. THORBURN AND CO., 15, John Street, New York, U.S.A.

THE QUEEN'S SEEDSMEN, READING.

Send for a PRICE LIST of
BLAKE'S SELF-ACTING
HYDRAULIC RAMS,

For Raising Water for the Supply of
Villages, Irrigation, Railway Stations, Mansions,
Fountains, Farms.

No Cost for Motive Power, which is obtained from the
Stream of Water passing through the Rams.

NO OILING OR PACKING REQUIRED.

Made in sizes to raise from 300 to 100,000 Gallons per day.

WILL FORCE TO A HEIGHT OF 1,500 FEET.

This advertisement will
appear again in three weeks.

This Ram will raise a part of the same water that works it, or will raise pure water from a well whilst it is worked by a stream of impure water.

TESTIMONIALS.

From the Right Hon. T. SOTHERN ESTCOURT, *Estcourt Park, Gloucestershire, September 6, 1875.*

"You will be glad to hear, as I am to tell you, that your Self-acting Hydraulic Ram has worked exceedingly well and continuously since it was erected, more than twelve months ago. It is, in fact, perfectly successful."

(The delivery pipe in the above case is 4200 feet long, with 100 feet rise.)

From Captain TOWNSEND, *Wineham, February 10, 1877.*

"In answer to your inquiry, I am glad to say the Hydraulic Ram you sent me in November, 1875, is working exceedingly well, and gives no trouble. It will work when quite immersed, as it has been several times during the floods this winter, forcing up water through a delivery pipe 900 yards long at the rate of 80,000 gallons per day, although you only promised 50,000."

From JOHN BARNES, Esq., *Contractor, Chatham and Helli-field Railway, Contractor's Office, March, 1877.*

"Dear Sir,—I have the pleasure to inform you that the three Hydraulic Rams you erected for me on this contract about two years ago, have continued to work very satisfactorily, without requiring any repairing. With a fall of 5 feet sufficient water has been raised daily by each Ram to supply two of my locomotive engines: they have fully answered my expectations and all that has been said of them."

Deanwater, Wilmslow, November 20, 1873.

"Dear Sir,—In answer to your inquiries respecting the Hydraulic Ram you supplied me with six months ago, I beg to state that I am more than satisfied with it, as it is in perfect order, sending up to the top of the house about 2000 gallons of water in the twenty-four hours, whereas you only contracted to deliver in that time 500 gallons. I have, therefore, every reason to be well pleased with your work, and more especially as I had Ram supplied me by another maker which could not send up a single gallon of water to the height required, and a second maker informed me that no Ram with a fall of 3 feet could send up water to the distance required, namely, 120 feet. But yours is an accomplished fact, and does its work most effectually.—I am, yours truly, L. HAMMER."

From Mr. THOMAS MASON, *Aikincoates Hall, Colne, September 30, 1871.*

"Sir,—Your self-acting Hydraulic Ram gives me entire satisfaction; it has been at work about fifteen months, and has only been seen once during the last six months; it is forcing about 1400 gallons per day of twenty-four hours to a height of 194 feet."

From JOHN PENNINGTON, Esq., *Emmott Hall, near Colne, December 21, 1868.*

"Sir,—The Self-acting Hydraulic Ram you supplied me with nine months ago continues in excellent condition. It receives water from a spring through a 2-inch pipe, of which it forces 3500 gallons per day of twenty-four hours to a height of 90 feet, exceeding all you promised, and far surpassing the water-wheel and force pumps which it has displaced. Its cost is small, it occupies but little space (2 square feet), and in mechanical detail is simplicity itself. I have much pleasure in recommending it as a cheap and efficient method of raising water."

JOHN BLAKE,
ENGINEER, ACCRINGTON.

SATURDAY, NOVEMBER 17, 1877.

PLANT NAMES:

THEIR PRONUNCIATION.*

I. IN classical words, and in botanical names, and terms constructed upon classical models, there are usually as many syllables as there are vowels. So far, they are represented in the English names and words Anna, Phoebe, society, panorama, pictorial. The exceptions to this rule are as follows:—

(a.) When *u*, with any other vowel, follows *g*, or *q*, or *s*, the two vowels are run together, as in *Guarea*, *Quisqualis*, *Succicus*.

(b.) The diphthongs *ae = e*, and *oe = o*, are sounded as a single letter, as in *Aethusa*, *Hæemantus*, *Dracæna*, *Ceanthe*, *Anæctochilus*.

(c.) So also are the digraphs *ei = ei*, sounded like *i*, as in *Geissois*; and *eu = eu*, sounded like *u*, as in *Eugenia*. Single syllables are also constituted of the digraphs *ai*, *au*, *oi*, *ou*, with their contiguous consonant, as in *Ailantus*, *Laurus*, *Redoutea*, and in the adjective *dioicus*, *a*, *um*. Such words as *bromoides* and *festuoides* constitute a distinct set. In these the *o* and *i* do not form a digraph, but are sounded separately, for reasons which will be spoken of presently. Some other proper digraphs, sounded as single syllables, will also be spoken of presently.

II. Names consist of only one syllable, as *Glaux*, *Rhus*, *Phlox*. Of two syllables, as *Crocus*, *Bidens*, *Cornus*. Of three, as *Primula*, *Narcissus*, *Solanum*. Of four, as *Aralia*, *Polyanthus*, *Dendrobium*, *Rhododendron*; of five, as *Anæctochilus*, *Didymochlæna*, *Eriophorum*; or of six, as *Tetragonolobus*. Names of Natural Orders sometimes run to seven, as in *Chamælauciaceæ*. Adjective terms, employed to distinguish species, run from two to seven, as *albus*, *arvensis*, *poeticus*, *depauperatus*, *angustifolius*, *caryophyllaceus*.

When a word consists of more than one syllable, the constituent members are not called the first, second, third, fourth, &c., but are reckoned backwards from the concluding one. The syllable which immediately precedes the last is called the *penult*; and when there are more than two, the syllable preceding the penult is called the *antepenult*.

In *Nymphæa*, *Phaseolus*, and *Didymochlæna*, the *phæ*, the *o*, and the *chlæ*, are the respective penults; while the antepenults are the *Nym*, the *se*, and the *mo*.

If a word consists of only two syllables, the name of penult is still employed, in this case denoting what would popularly be called the first. In *Bidens* and *Pinus*, the *Bi* and the *Pi* are the respective penults.

In order that an antepenult shall exist, of course the word must consist of at least three syllables.

Observe particularly, that it is either upon the penult or the antepenult that the accent invariably falls.

III. In words of only two syllables it falls, necessarily, upon the penult, as in *Crocus*,

* Great difficulty is often experienced by the uninitiated in the pronunciation of the names of plants. In many cases a set rule can be laid down, in other instances it is a mere matter of euphony or of custom, and sometimes it is quite arbitrary. Mr. Grindon's notes will, we hope, be found useful to gardeners and others perplexed by the difficulties of the subject. It must, however, be borne in mind that the Continental pronunciation of classical names is often very different from our own. Mr. Grindon's notes refer to the old rules of pronunciation till lately followed by all our classical scholars. It will be long ere the new system comes into general use. Eos.

Bidens, *Cornus*, *Pinus*, *Iris*, *Bromus*; *albus*, *ruber*, *nutans*, *major*, *minor*.

IV. When there are three or more syllables, the place of the accent is chiefly ruled by the measure of the vowel contained in the penult. (See V.)

(a.) When the vowel of the penult is long, the accent stays upon it, as in *Sola'num*, *Albu'ca*, *Papa'ver*, *Lapsa'na*, *Eri'ca*, *Anemo'ne*, *Cyathe'a*, *Didymochlæ'na*, *Metroside'ros*, *Luzuri'ga*; *crista'tus*, *macula'tus*, *officina'lis*.

(b.) But if the vowel of the penult be short, then the accent shifts to the antepenult, as in *Bet'ulus*, *Tor'tula*, *Til'ia*, *Trib'ulus*, *Mandrag'ora*, *Monot'ropa*, *Ornithog'alum*, *Caprifo'lium*, *Siphocamp'pylus*, *Spermacic'tyon*, *Aristolo'chia*, *ele'gans*, *grave'olens*, *auranti'acus*.

(c.) Unless the penult ends with a consonant, and the ultimate begins with another consonant, in which case the penult again keeps the accent to itself, as in *Narcis'sus*, *Napcl'ius*, *Rhododen'dron*, *Agrostem'ma*, *Cherophyll'um*, *Podophyll'um*, *Anigozan'thus*, *Amorphophal'lus*, *Myriococ'cum arven'sis*, *flaves'cens*, *Havanen'sis*, *Canarien'sis*, *pulverulen'tus*.

(d.) In diminutives, such as *Gladiolus*, the vowel of the penult is short; therefore, the accent falls on the antepenult, and we say *Gladi'olus*, *Lute'ola*, *Rhodi'ola*.

(e.) When the vowel of the antepenult is long by nature, it takes the accent as a matter of course, as in *Cle'matis*, *Ne'rium*, *Pro'tea*, *Cenothe'ra*, *Jasio'ne*, *Stratio'tes*, and other names, which in the original Greek have η or ω in the place indicated.

V. To ascertain whether the vowel of the penult be long or short, we refer, in the first instance, to the dictionary or the lexicon. When these fail to tell, we fall back upon comparison, the laws of euphony, and common-sense. Names, it must be remembered, are of various derivation, and to some extent the pronunciation is determined by their origin. Most of the old-fashioned generic names, to the number of about 300, *Viola*, *Narcissus*, *Anemone*, *Clematis*, *Gladiolus*, *Asparagus*, &c., with most of the old-fashioned specific appellations, such as *arvensis*, *maritimus*, *auricomus*, exist pure and simple, in either the lexicon or the dictionary, in their proper places, and with the proper accentual marks. With these, accordingly, all is straightforward.

The second class of names consists of those which have been framed in modern times, upon the models supplied in the above cited *Viola*, *Narcissus*, *Anemone*, &c., viz., by taking some such root-word as $\gammaερανος$, $πελαργος$, *stella*, *cinerea*, *arena*, and adding to it an ornamental Latin termination, the products being *Geranium*, *Pelargonium*, *Stellaria*, *Cineraria*, *Arenaria*, &c. These names are all simple, as opposed to compound, and when they end like those which have been quoted, invariably take the accent on the antepenult, *Gera'nium*, *Pelargo'nium*, *Stella'ria*, and so forth.

But when they end in *æa* or *ëum*, the accent falls on the penult, as in *Pimele'a*, *Calathe'a*, *Phle'um*, *Rhe'um*.

Adjectives formed upon original Latin bases, of the kind illustrated in *arena'ceus*, *a*, *um*, also have the accent upon the antepenult.

The names belonging to this section never need be mispronounced.

VI. The third and largest class of names, including both generic and specific, consists of the compounds contrived in modern times, still from classical bases, and upon the models supplied by the ancients in their *Trifolium*, *Rhododendron*, *Acanthus*, &c. To this class belong all such as *Tragopogon*, *Polypogon*, *Polyanthus*, *Anæctochilus*; *diandrus*, *leucophyllus*, *sessilifolius*. To find the pronunciation of the penult in these, we must look up the piece of the word in which the penult is contained. A very small amount of practice soon enables an attentive observer to distinguish a compound word from a simple one; to distinguish, for

example, between Geranium and Pelargonium, on the one hand, and Tragopogon and Polyanthus on the other. Nothing, at all events, is lost, and much is certainly gained, by being called upon to consider the matter intelligently and for one's self. To fail in finding Tragopogon in its entirety is a useful lesson, since we are then led to the presumption that the word is one of the compound class; the very shape of Tragopogon suggests its nature, and we look next, accordingly, for pogon, and are rewarded. So with the second portions of Poly-anthus, Anæcto-chilus, leuco-phyllus. Compound names, with long and rolling terminations of Latin fabric, such as Polypo'dium, Anictan'gium, Omphalo'bium, Polysipho'nia, invariably have the accent upon the antepenult. In hunting up the derivation and the signification of a word, of course, as with everything else that is worth doing, we are not to expect that, easy as the process soon becomes, it is to be accomplished without some effort, and the use of one's head; intelligently considering what is the object in view, the occupation soon becomes as facile as it is instructive.

If it be asked upon what authority the dictionary and the lexicon declare particular syllables to be long or short, the reply is that such is the teaching of the ancient Greek and Latin poets. Sometimes the authority sufficiently consists in the absolute or intrinsic nature of the vowel. *Leo. H. Grindon.*

(To be continued.)

New Garden Plants.

MASDEVALLIA FLORIBUNDA, *Lindl.*; *Masdevallia floribunda*, *Lindl.*, Bot. Reg. 1843, Misc. 112, M. Galeottiana, A. Rich. Gal. Ann. Sc. Nat., 1845, Janv., p. 17, and tab. ined. 3, f. 1! *Masdevallia myriosigma*, E. Morr., Belg. Hort. 1873, pp. 359, 361, 384, cum icone; *M. floribunda* var. *myriosigma*, E. Morr., l.c. 380.

This is a free growing plant with densely cæspitose stems bearing spatulate shining leaves of a rather thick substance. The very thin capillary peduncles are usually shorter in the wild specimens, but are longer in such cases when the leaves have been badly developed in Europe. The flowers have an abrupt chin, and the inferior sepals are rounded at the top and suddenly extended into a short tail, when the very small free part of the upper sepal is triangular, tapering by-the-bye into a tail. The tails are altogether of a pretty yellow, as is the back of the superior sepal, where the lateral sepals are much more pallid, whitish. Very numerous little brown spots are scattered over the lateral sepals and the back of the so called dorsal one, lighter outside, darker inside, vanishing as the flower fades, when it appears simply yellowish. This was, of course, the state in which Dr. Liodley saw it, put in a box. Petals white, with a triangular or a square production on the inferior side, and a keel on the blade, retuse at its top, with three teeth. The uoguculate lip is nearly heart-shaped at its base, constricted before the middle, and with a blunt apiculus at its tip, whitish with numerous brownish purplish spots, now with a green crescent-shaped spot before its apex. The column is unguiculate at each side of the top, and has a dark brown border.

This plant would seem, so far as our knowledge reaches, to be absolutely Mexican. It appeared in 1843 in the collection of John Rogers, Esq., of Sevenoaks, Perhaps it came from M. Galeotti, who gathered it 1840 near Vera Cruz. It is No. 5075 of his collection, and the M. Galeottiana of Achille Richard himself. He says "*fleurs lilas sur les chênes.*" This epithet "*lilas*" may be correct if we consider the numerous various colours of *Masdevallia infracta*, but it may well be a mistake from the flowers having been observed faded. I also had it from Galeotti in alcohol. Then it was collected by Liebold, from whom nine dried plants with numerous flowers are at hand. I also obtained it from the late M. Sartorius. Finally it was introduced by M. Makoy, of Liège, who informed me it was Professor E. Morren's *Masdevallia myriosigma*—and the celebrated Bromeliologist, indeed, quotes M. Makoy for the introduction of his new plant. It appears that this *savant* has a very narrow conception of what is a species among Orchids, so that he believes in very many species. Now as to the name (printed six times), *myriosigma*, it was the meaning of the Belgian *savant* to write *myriostigma*, I hope, since he says "*myriosigma*, which signifies with points." Now *sigma* signifies the letter σ in Greek, while *stigma* is a little spot or point. But this, indeed, is quite as unimportant in comparison to the incorrect representation. It gives us pretty well a rosette of leaves with a terminal umbel or corymb

FIG. 121.—COLLETIA SPINOSA—NATURAL SIZE; FRUIT MAGNIFIED.

of flowers. A strict morphologist would get a fever at the sight. And as to the flowers, they are at all events absolutely unlike those of *floribunda*, the sepals altogether tapering into the long tails. Analyses unintelligible. And yet our living plant, that flowered in profusion, comes from the same source; and the last evidence (which caused my note for *Gardeners' Chronicle*) is furnished by fresh flowers received from Mr. H. Veitch, who received them as *Masdevallia myriosigma* from M. Lamarche. *H. G. Rehb. f.*

interesting they should not be overlooked by planters who like variety and love plants. The *Colletias*, named after a French botanist, Collet, constitute a genus of dry spiny shrubs of the *Rhamnus* family, natives of Chile and other parts of South America. In habit some resemble Gorse, others Spanish Broom, others the little Rest-Harrow of our fields. Their branches are evergreen, mostly spiny, and bear small inconspicuous leaves and pretty little white

The degree of vigour, and therefore the size and to some extent the form of the branches, is thus subject to variation, as is also the pubescence, some forms being pubescent others glabrous. Great as the variation from seed doubtless is, we do not think there is any good evidence to show that the species next to be named is a variation from *C. spinosa*—at least within what we may term the historic period, though there is nothing very improbable in the idea.

FIG. 122.—COLLETIA CRUCIATA—NATURAL SIZE, WITH FLORAL DETAILS MAGNIFIED.

COLLETIAS.

A PLANT which, to use a familiar expression, created some sensation nearly thirty years ago, but which seems to have fallen from the recollection of all but a few, is *Colletia cruciata*. Some remarkably vigorous branches of it were shown at one of the recent meetings of the Linnean Society, where they attracted much attention, and as several specimens have reached us lately to be named, we think it may be serviceable to recal briefly what is known about it. We avail ourselves of the opportunity of mentioning some other species, for as they are all hardy and all

bell-shaped flowers, sometimes in great profusion. As we have said, they are hardy, and would make excellent lences, their spiny habit making them useful to "stop a gap" in a hedge. The best known species in gardens is probably the following:—

COLLETIA SPINOSA.—A formidable fellow enough, as will be seen by the figure (fig. 121), which is so characteristic that we need say no more about it, save to remind the reader that it has several aliases, e.g., *C. spinosissima*, *C. horrida*, *C. polyacantha*, *C. armata*, of Miers; *C. ferax*, of Gillies; *C. valdiviana*, of Philippi. These are, in our opinion, either synonyms, or trifling varieties of the originally described form.

C. CRUCIATA.—This is indeed a striking plant. Our figure (fig. 122) shows a branch of moderate size, but the specimens shown at the Linnean Society were much larger—larger indeed than any native specimens we have seen. The branches here form stout flattened triangular sharply-pointed outgrowths arranged in pairs, the pairs crossing each other at right angles. The texture is woody, the colour deep green. The little waxy-white bell-shaped flowers hang from tiny little stalks beneath the formidable spines. They have no corolla, and five short stamens attached to the throat of the white calyx. At the bottom of the flower tube there is, as in all the other species, a

little process, technically a "disc," rolled up like a volute, which secretes honey and indirectly serves in the fertilisation of the flower. This curious little disc is precisely similar to that met with in the bottom of the flower-tube of some Passion-flowers, and affords a good instance of close similarity of structure in two plants of widely different botanical kinship. The truth is, the end to be obtained is the same in both cases. The characteristics which are peculiar to or distinctive of plants are congenial and hereditary, but an organ devised to secrete honey and attract insects is often a secondary or adaptive character, which does not make its appearance at birth, so to speak, but subsequently, when the requirements of the plant demand its appearance. However, this is a little bit of botanical philosophy which planters will not care for. Let us, for their behoof, state that to our knowledge the plant is quite hardy near London, that its white flowers are now in full bloom, and that its striking appearance never fails to excite curiosity. One drawback it has, for which we can offer no good reason, and that is a tendency for some of its branches to die off—how or why we know not—we only know that the dead branches thrust into a gap in a hedge, formerly much traversed by suburban cats, have proved very effectual in barring access by that route to such undesirable visitors. The plant is a native of Maldonado, Monte Video, &c., and was originally described from wild specimens by the late Sir William, then Dr. Hooker, in the *Botanical Miscellany*, vol. i., t. 43, p. 172.

By oversight or forgetfulness, the late Dr. Lindley, nearly twenty years later, described the plant in vol. v. of the *Journal of the Horticultural Society of London*, (1850) as *Colletia biconensis*. According to the account there given, Sir Philip Egerton noticed the plant at Bicton, and asking the gardener, the late Mr. James Barnes, as to its history, received for answer that it was a seedling variety raised by himself from *C. horrida* (spinoso). At first Mr. Barnes did not remember the history of the plant, but on being reminded by his foreman he made the just quoted statement. As we have said, the natural variation of plants is so great that there is no absolute impossibility in Mr. Barnes' statement, but when we consider that the wild plant was well known and figured twenty years before, that plenty of wild specimens are in the herbaria, and that Mr. Barnes' recollection was at first not very clear on the matter, and that, lastly, though *Colletia spinosa* ripens its seeds pretty freely, the variation has not been reproduced, there is, we think, ample ground for considering the plant to be a truly wild plant and not a seedling from *C. spinosa*. The fruits of the two species are very much alike, and might readily be confounded.

C. SPARTIOIDES, of Bertero, is a native of Juan Fernandez, and if not already introduced should be. Its long, slender, flattened, virgate branches render it desirable. We only know it in a dry state.

C. EXSERTA, of Klotsch, is a Brazilian species, very similar to *C. cruciata*, but with more slender lanceolate branches. This would probably be too tender for outdoor culture.

C. ULICINA, Hook., is a charming little plant for those who like curiosities. It is a low growing, dense, intricately branched little shrub, the smaller branches very slender, stiff, and spiny, exactly like the dwarf Gorse, *Ulex nanus*, but densely pubescent. It is a native of Chile.

C. DUMOSA, of Miers, also a native of Chile, is very like *C. spinosa*, but denser and more pubescent.

C. FEROX, of Gillies, is we believe the same as *C. spinosa*.

C. PARVIFLORA, gathered in the Galapagos by Darwin, is a very curious species, in the way of *C. spinosa*, but with more elongate curved branches. It would probably succeed in the conservatory or winter garden, but is not, so far as we know, in cultivation.

C. VALDIVIANA, of Philippi, is probably only a form of *spinosa*.

C. NANA, of Clos, the *Ochetophila prostrata* of Miers, is a very curious species, very desirable for rockwork. It is a dwarf, compact, rugged, woody little shrub, the branches grey and rough, spreading on the soil or scarcely raised above it, and densely covered above with minute rather thick leaves. A little gem for the connoisseur, but we fear not in the country.

Lastly we may mention *C. SERRATIFOLIA*, sometimes called *Discaria serratifolia*, figured by us on a previous occasion (see p. 619), and which in some seasons at Kew

is a perfect sheet of bloom—very beautiful, but we never saw it out of Kew, though it is in a frequented part of the pleasure-grounds, where in the season it must be seen by thousands of the public, and probably hundreds of gardeners and landscape gardeners.

Other plants of near alliance are *Retanella ephedra*, sometimes called *Colletia ephedra*; *Trevoa trinervis*, and *Talguenea costata*, of Miers, which to the general habit of those before-mentioned add the charms of silvery leaves. We trust we have given a few hints alike to planters and to our enterprising nurserymen, who have not yet got all the good plants.

CALANTHES.

THE season of flowering of the Calanthes in the stoves is again at hand. In this dull weather, when every flower outside is washed out or broken by storm, these indoor subjects repay the labour upon them, as they are clean, and decidedly of the first class. Even when the Chrysanthemums are in flower—and a fine show they make from their variety of colours—for purity it may be said they do not equal the Calanthes, nor do they last so long; still, the Chrysanthemums are plants which every one can grow, while the Calanthes are truly stove subjects, and cannot with any great degree of success be treated out of their own fixed quarters. The flower-spikes of the Calanthes are well adapted for cutting, as they last well; but when the whole flowering plants are set in a cool place, they invariably soon suffer; so that if flower-spikes are so good for decoration, or single flowers lasting fairly compared with other flowers, the plants themselves when in flower are best not much removed out of their flowering quarters. Winter-flowering things, such as *Eucharis amazonica*, when in bloom, do well removed to the conservatory; but if fine pots of Calanthes are taken there in a similar way, the result may be that before long the flowers get spotted as a result of the cold or damp, and if they remain too long there the same effects may reach the bulbs, and the consequence may prove a loss in every way.

A very pleasant show of colour can be made in the plant-stove with the three varieties—*Calanthe vestita-rubra*, *C. Veitchii*, and *C. vestita-luteo-oculata*. The first-mentioned was introduced some time before the others, and may be considered an old plant, but still in point of merit it stands at the top of the list. *Calanthe Veitchii*, being of such a beautiful pink, is well adapted for showing off the others, but generally it may scarcely prove so fine as *C. rubra*. It is a more upright grower, and lasts a longer time in flower, which is an additional advantage in its favour. To cultivate these Orchids fairly well, and even what might be termed very successfully, no Orchid-house, strictly speaking, is required—the ordinary treatment, as far as atmospheric conditions is concerned, that is given to stove plants, is quite sufficient. When grown amongst stove and ornamental plants largely, perhaps the only objection to them is, that when they are not in flower they are very ordinary looking subjects.

Perhaps as good a plan as any of treating these Orchids is to plant from six to eight good bulbs in a 12-inch pot, when, if the variety be *C. vestita-rubra*, and the plants do well, they will throw about a dozen spikes of flowers, and these being nicely curved gives a good proportion to the whole. In some cases when the plants are in flower a good deal of the foliage has died away, but if the leaves and bulbs have been kept clean of brown-scale, which they are subject to, and the bulbs not dried off too soon, a fair coating of leaves can be had on the plants when they are at their best.

As might be expected these plants in summer do best under liberal treatment as far as water and sunlight are concerned, and as well as this a good rich compost for them to grow in tends to insure a good display of flowers. As is the case with all plants that require copious watering in the growing season, the drainage should be made thorough. If, for example, a 12-inch pot be used for Calanthes, about half may be filled with crocks, so as to make the operation good. A compost of turfy loam and peat, and lumps of dry cow-dung mixed together suits very well. When the compost is being put in the pots it is best made higher than usual—rounded up towards the centre. When the bulbs are set on the surface a sprinkling of sand may be put over the soil, which by the after watering will be washed down. Assuming that bulbs have just been planted when they are starting, they

will not require so much water till the foliage is fully on, when as a matter of course they are in full vigour and require it liberally. Towards the end of the year they require much less, still it is best when their season of rest is approaching—their time of flowering—not to withhold the water too soon but gradually, according to the foliage; as it naturally dies away the natural season of rest asserts itself. By the time every bit of green foliage is about off the flower-spikes will be getting well spent, and when they are off a period of thorough rest from apparent growth will be the result. While in that state they require no water, and may be set all together in some corner of the stove. By the time they have had their allotted time of rest they will show in due course that they are in keeping with the season, ready to start when spring returns. *R. Mackellar*. [Our correspondent has favoured us with very fine spikes of the varieties he mentions. Eds.]

THE BARNET AND HIGHGATE NURSERIES.

THE Barnet Nursery, established by the late Mr. William Cutbush, had a good reputation under his management for its stocks of stove and greenhouse plants, and New Holland plants especially, which were grown, and well grown, in considerable numbers; and we were pleased to learn, when we paid a visit to the nursery a short time ago, that since it came into the possession of his brother, Mr. James Cutbush (Messrs. William Cutbush & Son) it has lost none of its former reputation, but has, on the contrary, we think, somewhat enhanced it. The nursery is situated about half a mile from the High Barnet Station, and a mile and a-half from Barnet, on the main line of the Great Northern Railway, and is especially interesting at this season both to planters and those who are getting in their annual supplies of winter and spring flowering hard-wooded plants. Heaths and Epacris are largely and especially well done, the number of the former annually grown into a saleable size, in the regulation 48-sized pot, being no less than 30,000. The species and varieties cultivated are about 130, but the sorts grown to the largest extent are the popular *E. hyemalis*, *E. Wilmoreana*, and *E. Siodryana*. The last named is not usually considered one of the easiest plants to grow, but as seen here it is as free a grower and bloomer as *E. hyemalis*. It is a circumstance worthy of remark that all the Heaths here are better set with flower-buds this season than they have been for several years [Is this general?], and certainly a more cleanly and vigorously grown lot could not be desired. Amongst the winter flowering sorts now in bloom we noted the pretty small-flowered *E. gracilis* and *E. caffra*, and *E. arbuscula*, a species not much grown by the trade, but a nice growing and free flowering subject. That certain plants naturally do better in some places than others is a truism which we allude to only as it applies to certain Heaths which do especially well in this nursery, and amongst which we may note the spring flowering variety of *E. gracilis*, the dark flowered *E. hybrida*—a good thing, *E. assurgens*, *E. persoluta alba*, *E. pyramidalis*, &c. The Epacris looked as well as the Heaths, and we need say no more of this genus than that the collection includes all the best species and varieties, some sixty in number.

The collection of Camellias is a very complete one—over eighty sorts, and the plants range in size from well-furnished pyramids 9 feet high to small stocky little specimens in 48's, the sorts most favoured being the old double white, *C. imbricata*, *C. fimbriata*, and *C. Mattbotiani*, and these are grown in quantity. Next to the Camellias a grand lot of Solanums came under notice. These solely consisted of *S. pseudo-capsicastrum*, of which about a thousand are grown from cuttings into a size suitable for decorative purposes, and handsome they are with their full crop of scarlet berries. For table decoration a nice lot of half standard specimens in pots of *Aucuba japonica* vera are annually prepared, and to judge from their neat habit and excellent crop of coral-red berries, we should think they would have a decidedly good effect on the table. Nothing could be more cheerful or pleasing during the dull winter months, and if table plants must be provided, it is well to know that bardy plants of this character can be had for the purpose.

In several of the houses we noticed quantities of handsome young specimens of the graceful narrow-leaved *Dracena australis*, and a fine lot of young

plants of the old and favourite *Ardisia crenulata*, beautifully set with berries. This and *Darwinia* (*Hedaroma*) *tulipifera* may almost be said to be specialities, so well are they done in quantity. The last-named are in sizes from the half specimen downwards, and a particularly healthy well-furnished lot they are, as a result of a system of treatment directly opposed to coddling of any kind. *Phœnocomas* are also represented in a first-rate style; and the same remark applies with equal force to the examples of *Dracophyllum gracile*, which are noticeable on account of the numbers grown and their strong robust appearance; and of *Boronias pinnata* and *serrulata*, beautifully furnished samples. The true *Gompholobium polymorphum splendens*, *Leschenaultia formosa*, *Witensia corymbosa*, *Statice profusa* and *S. Holfordii*, *Eriostemon scabrum* and *pulchellum*, *Aphelexis*, *Tetrathecæ*, *Chorozemas*, *Pimelcæ*, *Corræas*, *Acacias*, and *Bouvardias* are also largely and well done. So, too, amongst stove plants are *Eucharis amazonica* and *Epiphyllums*, of which latter the collection includes some fourteen sorts. *E. tricolor* is the most extensively grown of any. *Azaleas* in small sizes also claim a considerable share of attention, and so do such useful fine-foliaged decorative plants as *Dracænas*.

be seen in great numbers, and the stock is large of plants from 4 to 5 feet high, and especially good in the case of *Ilex Hodginsii*. The *Hollies* are succeeded by *Cedrus Deodara*, a fine lot, from 4 to 5 feet in height; a good quarter of *Platanus orientalis*, and a grand lot of young *Limes*, clean standards, from 8 to 9 feet in height. Weeping *Willows* also claim some notice by reason of the fine quality of specimens of *S. americana* and the well-known *Kilmarnock* variety. Excellent stocks of *Yews*, *Pinus Cembra*, *Tamarix gallica*, *Ghent Azaleas*, standard *Portugal Laurels*, common *Laurels*, and the *Caucasian*, *Colchic*, and round-leaved varieties; together with *Irish Ivies*, of which the stock of plants consists of about 8000, from 8 feet to 9 feet high. Space forbids our mentioning all the subjects grown here, and we think we have said enough to convince any one that a visit to the nursery would not be time ill-spent.

The Highgate Nursery, which has been made famous by the lead which it took some years ago in the cultivation of the *Hyacinth* and other spring-flowering bulbous plants, has been in the possession of the Messrs. William Cutbush & Son since 1820, and it was a nursery then. Amongst hardy sub-

large size for planting; most noticeable amongst which are tall handsome furnished pyramidal specimens of the *Colchic*, *Caucasian* and round-leaved *Laurels*. *Aucubas* are also done in quantities, and amongst these we may note *A. rotundifolia* as a distinct and ornamental subject.

The present is not a particularly good time of year to see the houses, as everything requiring protection has been got into winter quarters; but we noted a very useful selection of the various stove and greenhouse plants for which there is a demand, and particularly a fine lot of half-specimen *Azaleas*, and a grand stock of *Bouvardias* in all the leading kinds. Double white *Primulas* we also saw were done well, and we may fittingly conclude this notice, imperfect as it is, with a reference to the stock of *Mignonette*, which is well grown, and has been sown for the fifty-seventh year in succession, in the same frame, and on September 1. The Highgate Nursery is one of the neatest kept that it is our pleasure to visit, and its management is much to the credit of its present proprietor.

PROTECTING WINTER BROCCOLI.

THE dry weather that set in during August, and continued for some time after, caused a severe check to the growth of all winter and spring Broccoli, but the heavy rains we have since had, together with an exceptionally close, warm state of the atmosphere, have set them growing almost as freely as if it were spring. Although at first sight this would appear to give promise of an abundant supply the reverse is likely to be the case, for unfortunately this increase in size and the extraordinary push they have recently made is anything but favourable to their standing the winter in safety. Those who have had much experience in growing Broccoli must have observed the great difference there is in the hardness of the different kinds, much of which is due to their habit of growth, as it is only such as have close compact leaves and hard woody stems that can endure a continuance of severe frost. The expansive force of this is so great that, as is well known, it will even burst strong iron pipes when left full of water where they can be acted on, and it has the same effect on the gorged sap-vessels of Broccoli when caught in the soft succulent state they now are.

Although the large growers for the London markets, who are considered the best vegetable gardeners, do not as a rule go to the trouble of heeling theirs in, there can be no question that the practice is a good one and has much to commend it, especially in seasons like the present, when the growth they should have made early in the autumn has been deferred until now. The heeling-in, by the salutary check it affords through breaking numbers of the feeders, in a measure cuts off the supply of moisture, and thus causes the tissues to become more hardened, so that when frost occurs they are in every way in a better condition to meet it. In severe winters I have frequently noticed that starvelings near trees have stood quite uninjured when all of the same kinds grown in richer ground close by have been totally destroyed, thus proving conclusively that the firmer and more woody texture they had was the cause of their immunity. Like most other important operations connected with gardening that have beneficial effects under certain conditions, there is a reverse side to the heeling-in of Broccoli, and that is that it reduces the size of the heads, but this to those whose business it is to keep up a supply for their employer's table is not so much a matter of consideration, as it often becomes a question of these or none at all, which is more than ever likely to be the case next year. Those therefore who would insure what they have should lose no time in adopting measures to secure their safety.

The best way to proceed is to dig out a trench close along one side of the outer row and then to thrust in the spade and heel them over on their side, digging the soil from between to cover their stems, when the next row can be laid over in like manner, and so on to the end. Broccoli so treated are proof against almost any amount of frost as the leaves fall flat over on the ground, on which they lay close when frozen or flaccid and so protect the hearts in the most effectual way, whereas when the plants are standing they droop down the stems and leave the crowns quite at the mercy of the weather. I have been much struck by the snug appearance of the one compared with the

FIG. 123.—COLLETIA (DISCARIA) SERRATIFOLIA. (SEE P. 618.)

Another subject grown in quantity in small pots for table decoration is the handsome *Grevillea robusta*, and for early forcing *Daphne indica rubra*.

While the hard-wooded plants are in their summer quarters in pits and frames, the houses are employed in the culture of pot Vines, of which a goodly number are annually grown to meet a ready sale.

In the outdoor department we noted a nice collection of Ivies, which is being rapidly worked up; and various breaks of neatly-trained fruit trees, especially *Apricots*, *Peaches*, and *Nectarines* and *Pears*, but these subjects are only grown in limited numbers here—this department being better done along with *Roses* and various hardy shrubs at the branch nursery at Finchley, where some seven acres are devoted to them. *Violets* do well here on the cool soil, and the staple sorts are the *Giant*, *Neapolitan*, and *Russian*, coming into flower very freely. The leading speciality amongst hardy plants is, however, the variegated *Hollies*, of which there is here a larger collection than we have seen anywhere in the neighbourhood of London. The plants are of all sizes, and good in quality. *Golden Queen* is the most largely grown of all, and next perhaps in importance is *Waterer's golden* variety, another one named *marginata argentea*, and the variegated *Handsworth*. *Green-leaved* kinds are also to

jects that have always been done well here is the *Bay Laurel*, which grows to surprising dimensions in the neighbourhood; and it is a remarkable fact that all the plants that have been sold from this nursery have been propagated from one set of "stools," and that set has occupied the same position in the nursery as it did when the late Mr. William Cutbush bought the place in the year before mentioned. *Evergreen Oaks* form another speciality, and the stock of these, we need scarcely say, is a good one. It is a difficult subject to transplant, but this difficulty is got over by growing them in large pots; and specimens may be seen in such pots, up to 7 and 8 feet high. We also noticed a nice lot of standard *Bays* with close filled heads; a varied and interesting assortment of wall climbers, *Tree Ivies*—very useful subjects inasmuch that they are very ornamental and stand smoke well. Of *Weeping Elms* and *Weeping Poplars* we also noted some fine examples; together with a good batch of standard *Mulberries* from 7 to 8 feet high, and the like of which are not to be found everywhere. A large trade is done in small hardy plants, for potting up for window decoration in winter, and for planting in town gardens. These include various *Conifers* such as *Thuja aurea*, *Laurustinus*, various sorts of *Euonymus*, of which it is difficult to get enough to meet the ever increasing demand. Many subjects are also grown to a

other, especially after a slight fall of snow, when those not heeled in have stood like scarecrows, while the others hespoken comfort and safety under their covering. With such early sorts as Snow's, Osborne's & Backhouse's the best plan is to dry them entirely up with good balls and to lay them in some warm, sheltered, sunny border where they can be covered with long litter or Fern, otherwise the tender white flowers are sure to become sufficiently touched to cause discoloration or spoil their flavour.

For late work there is nothing like growing well tried hardy kinds, such as Cattell's Eclipse, which is short on the leg, and has a stem almost as hard as a stick, of a sturdy habit, and bears nice close compact heads, and is altogether a most valuable variety, and one that is deserving of extensive cultivation. In a general way, Broccoli are grown much too close together for them to acquire that solidity of stem and power of endurance they would attain were they allowed more room so as to let in plenty of light and air between them. If this could be afforded, and instead of being planted in loose heavily manured land they were made to follow some exhausting crop without any digging or other preparation beyond the necessary cleaning, the growth they make would be built up firmly, and if such large heads as might be obtained under a more liberal regimen were not produced, there would be no loss through the shattering effects of frost, which after a time like the present is much to be dreaded amongst the vegetable crops, as most of these are just now in a soft succulent condition and as tender as they can well be. ♀. S.

THE GENUS AGAVE.

(Continued from p. 558.)

SERIES II.—CARNOSO-CORIACEÆ.—Texture of the leaf more fleshy and flexible than in the Coriaco-carnosæ. End-spine small and scarcely pungent. Teeth small or absent.

Group VII. GEMINIFLORÆ.—Edge of the leaf splitting off with threads.

This group represents the Filiferæ of the Coriaco-carnose series, and contains a single species only.

6r. *A. (Littæa) geminiflora*, Gawler, in Brandes' Journ. iii., t. 1; Bot. Reg., t. 1145; Spin, in Suppl. Cat. Hort. Sebast. (1823), p. 8, with a figure; Reich., Ic. Exot., t. 209—210; Kunth, Enum., vol. v., p. 831; Jacobi, Monogr., p. 160; *Littæa geminiflora*, Tagliabue, in Bibl. Ital., i., 100.—Acaulescent. Leaves 200—300 in a very dense rosette, narrow linear, 1½—2 feet long, ½—¾ inch broad at the middle, bright green, both faces convex, not striated, the centre ½ inch thick, the base dilated to a breadth of ½ inch and a thickness of ¼ inch, the pale edge splitting off into thin threads, the tip not pungent, the leaves narrowed gradually to the point, all except the innermost curving over. Scape reaching a height of 18—24 feet, 3 inches thick at the base. Flowers in a dense spike, which is 6—8 inches in diameter when expanded; bracts as long as the flowers, subulate from a deltoid base. Perianth 1½—2 inches long including the ovary, reddish brown, the lanceolate spreading segments as long as the tube. Filaments twice as long as the segments, inserted at the throat of the tube; anthers ½—¾ inch long; style exerted. Capsule oblong-trigonus; seeds discoid, black.

A native of Mexico, said to have been introduced at the end of the last century. It first flowered in the year 1815 in the garden of Count Von Litta at Mailand, in honour of whom the genus *Littæa* was constituted by Tagliabue. The figure and description given by Spin in 1823 are so full and accurate that they leave nothing to be desired. As a species it stands far apart from any other. There are varieties with pale green and dark green leaves, and the filæ are variable in length and quantity, and rarely nearly or quite suppressed. *Agave Taylori*, Hort. Williams, of which we give a figure (fig. 125), is stated to be a hybrid between *geminiflora* and *densiflora*, but in character it comes very much nearer the former. It was exhibited at the Royal Botanic Society in March, 1874, and will be found noticed in our first volume for 1874, p. 418.

Group VIII. ALOIDÆÆ.—Edge of the leaf furnished with distinct deltoid teeth ½—¾ inch long. This is by far the largest group of the Carnoso-coriaceæ series. The only group of the Coriaco-carnosæ with which there is any danger of confusing its members is No. V., Rigidæ. From these Rigidæ the Aloidæ differ by their softer more pliable texture and by the end-spine being so weak as to yield readily

to pressure, but some of the species are so intermediate in character that their position between the two is doubtful.

* Leaves oblong-spathulate.

62. *A. regia*, Hort. Saunders; fig. 124.—Acaulescent. Leaves 12—15 in a rosette, oblong-spathulate, 14—15 inches long, 4 inches broad at the middle, narrowed to 2 inches above the base, bright green, with a non-pungent brown tip ½ inch long, the centre ½ inch, the base ¾ inch thick; the face flat, the prickles moderately close, deltoid, brown, and horny, the central ones spreading, one line long, the upper ones ascending, the lower ones deflexed. Inflorescence unknown.

Native country and history not known to me. I have seen it in the Reigate collection, and there is now a plant at Kew which was received from Linden in 1872.

63. *A. melanacantha*, Lemaire; Jacobi, Monogr., p. 117.—Acaulescent. Leaves about 1 foot long, 4 inches broad at the middle, narrowed to 2 inches above the base, oblong-spathulate, a light opaque green, the outer ones reflexing, the end-spine short and brown, the teeth somewhat distant, minute, deltoid-cuspidate, brown, deflexed. Inflorescence unknown.

Country probably Mexico. Described by Jacobi from a plant exhibited by De Smet at the Ghent exhibition of 1863. I have never seen it in any of the English collections.

64. *A. rudis*, Lemaire; Jacobi, Monogr., p. 118; *A. Malinezii*, K. Koch.—Shortly caulescent. Leaves

FIG. 124.—AGAVE REGIA.

oblong-spathulate, reaching a length of 15 inches, 5—6 inches broad at the middle, narrowed to 2 inches above the base, a light opaque green, the end-spine short, chestnut-brown, the face concave, the margin repand, the teeth moderately distant, horny, chestnut-brown, recurved. Inflorescence unknown.

A native probably of Mexico. Described by Jacobi in 1864, from a specimen in the collection of Herr Tonel, of Ghent. I have never seen it in England.

65. *A. Laurentiana*, Jacobi, Monogr., 254.—Acaulescent. Leaves moderately numerous, oblong-spathulate, 1½—2 feet long, 5—6 inches broad above the middle, narrowed to 3 inches above the dilated base, the face opaque green and deeply concave, the end-spine short, stout, and brown, the margin slightly repand, the teeth minute, crowded, deltoid, straight, horny and chestnut-brown. Inflorescence unknown.

A native probably of Mexico. Described by Jacobi in 1865, from a plant in the collection of Herr Laurentius at Leipsic. I have not seen it in England.

66. *A. Ofoyana*, Hort. Belg.; Jacobi, Monogr., 116.—Acaulescent. Leaves 25—30 in a rosette, oblong-spathulate, bright green, 1½—2 feet long, 4—5 inches broad above the middle, narrowed to 3 inches above the base, the base 1 inch, the centre ½ inch thick, the face deeply concave, the end-spine ½ inch long and sub-pungent, the teeth moderately close, deltoid, chestnut-brown, ½—¾ inch long. Inflorescence unknown.

A native of Havana. Described by Jacobi, in 1862, from a specimen in the collection of Madame Legrelle d'Hanis at Antwerp. It is included in Mr. Saunders'

series of photographs, and my notes were taken from a specimen in his collection in 1872.

67. *A. (Littæa) Celsiana*, Hook., in Bot. Mag., t. 4934; Jacobi, Monogr., p. 165.—Acaulescent. Leaves 20—30 in a rosette, oblong-spathulate, 1½—2 feet long, 4—5 inches broad at the middle, narrowed to 2½—3 inches above the base, persistently glaucous, the point hardly at all pungent, the face flat in the middle, the base ¾ inch, the centre ½ inch thick, the crowded lanceolate spines very unequal in size and shape, sometimes two confluent, only the largest brown and horny at the top, the rest all green, those of the lower two-thirds of the leaf deflexed, the border of the lower part of the leaf undulated. Scape 4 feet long, the lower bract leaves lanceolate, the upper ones subulate. Flowers in a dense spike, 1 foot or more long, and 6—8 inches in diameter when expanded. Perianth 2 inches long, including the ovary, the limb tinged purplish brown on the outside, the ovary ¾ inch long, the oblong lanceolate-spreading segments exceeding the tube. Filaments 2 inches long, inserted at the throat of the perianth-tube. Anthers ½—¾ inch long. Style reaching to the top of the stamens. Capsule oblong.

A native of Mexico. Described by Sir W. Hooker from a specimen that flowered at Kew in May, 1856, received from Monsieur Cels, of Paris, after whom it was named. In the English collections it is the commonest and best known of all the broad-leaved Aloidææ.

68. *A. (Littæa) Ehrenbergii*, Jacobi, Monogr., p. 136; Nachtrage, i., p. 43.—Acaulescent. Leaves moderately numerous, oblong-spathulate, 1½—2 feet long, 5 inches broad above the middle, narrowed to 2½ inches above the base, an opaque rather glaucous green, the face concave, the base very thick, the end spine short and brown, the prickles crowded, minute, deltoid, brown at the tip. Scape 4—5 feet high. Perianth, including the ovary, 1½ inch long; ovary oblong, ½ inch long; segments linear-oblong, above ½ inch long. Filaments above 2 inches long; anthers ¾ inch long. Style 2½ inches long.

A native of Mexico, described by Jacobi from collections at Berlin and Erfurt in 1864, and exhibited by Verschaffel at Amsterdam in 1865. It flowered with Herr Allardt at Berlin in 1867. I have not seen it in England. Judging from the description, *A. Legrelliana*, Jacobi, Mon., p. 253, may be a variety with a broader (6—7 inches) leaf.

69. *A. Lindleyi*, Jacobi, Nachtrage, i., p. 37.—Stem 1½ foot long below the tuft of leaves. Leaves numerous, oblong-spathulate, 6—7 inches broad at the middle, narrowed to 3—3½ inches above the base, very thick, flat in the middle, glaucous, the end-spine dark brown, the margin scarcely repand, the close deltoid teeth with a horny black tip. Inflorescence unknown.

History unknown. Described by Jacobi from a specimen seen in the collection of Mr. Saunders about 1867. I fear the plant is now lost, as I have not met with it either at Reigate or in any other English collection. ♀. G. Baker.

THE EARTHWORM IN RELATION TO THE FERTILITY OF THE GROUND.

FROM observations extending over a number of years, M. Hensen has been led to the conclusion that infertile undersoil is rendered valuable by the action of worms in two ways, viz., by the opening of passages for the roots into the deeper parts, and by the lining of these passages with humus. This will be more fully understood from the following facts regarding the life-habits of the worm (*Lumbricus terrestris*) given in M. Hensen's paper in the *Zeitschrift für Wissenschaftliche Zoologie*.

It is known that the adult animals in wet weather come up to the surface by night, and, with their hinder end in their tube, search the ground round about. They then draw whatever vegetable material they can find into their tubes—falling stems and leaves and small branches. In the morning one then finds little heaps of plant-fragments projecting at various parts of the surface, and each of them penetrating the tube of a worm. On closer examination it is found that the leaves have each been rolled together by the worm, and then drawn into the tube in such a way that the leaf-stalk projects. The portion of the leaf in the tube is moist and softened, and only in this state are plants consumed by the worm. There are distinct indications that the worm gnaws them, and after some days the meal is ended. The food is never

drawn deeper down into the ground. In digging the ground at various seasons it was only very rarely that plant remains were found in the subsoil, and probably they got there by accident.

With reference to the structure of the worm-tubes, some interesting facts were established in these researches. In humus their character is difficult to make out, owing to the looseness of the mass. In sand they proceed almost vertically downwards 3, 4, or even 6 feet, whereupon they often extend some distance horizontally; more frequently, however, they terminate without bending. At the end of the tube the worm is found with his head upwards, while round about him the tube is lined with small stones. On the sandy wall of the tube one observes more or less numerous black protuberances which make the sand fertile. These are the secretions of the worm,

and it finds moist, loose, fertile earth in abundance.

The question whether all roots found in the under-soil have originally grown in the tubes made by the worms, cannot be answered with certainty. It is certain that the roots of some plants penetrate themselves the sand, but not to great depths. M. Hensen is of opinion that the tap-roots, and in general such root-forms as grow with a thick point, can force a path for themselves, while the fine and flexible suction-roots have difficulty in obtaining a path into the depths other than what has been previously made for them. Roots of one year's growth especially can penetrate deep into the subsoil only where there are earth-worms.

A microscopical comparison of the earth deposited

humus, 1 cm. in height (rather less than $\frac{1}{2}$ inch), and in the sand were numerous worm-tubes partly fresh, partly with a humus wall 3 mm. thick, partly quite filled with humus.

Counting, when an opportunity offered, the open worm-tubes in his garden, M. Henson found at least nine in the square foot. In 0.15 square metre two or three worms were found in the deeper parts each weighing 3 grammes (1 gramme = 15 grains); thus in the hectare (1 hectare = 2 $\frac{1}{2}$ acres nearly) there would be 133,000 worms with 400 kilos. weight. The weight of the secretions of a worm in twenty-four hours was 0.5 gramme. While these numbers are valid only for the locality referred to, they yet give an idea of the action of this worm in all places where it occurs.

The assertion that the earthworms gnaw roots is

FIG. 125.—AGAVE TAYLORI, HORT. WILLIAMS. A GARDEN HYBRID BETWEEN A. GEMINIFLORA AND A. DENSIFLORA.

which, after being removed out of a tenanted tube, are found next morning replaced by fresh matter. They are observed after a few days, when a worm is put in a vessel with clean sand, and allowed to make a tube for itself. Older abandoned tubes are pretty regularly lined with the earth formed by the worm, and some passages are densely filled with black earth. This black substance appears to diffuse somewhat into the sand.

In about half of the tubes, not quite newly made, M. Hensen found roots of the plants growing at the surface, in the most vigorous development, running to the end of the tube and giving off fine root-hairs to the walls, especially beautiful in the case of cereals. Indeed such tubes must be very favourable to the growth of the roots. Once a root-fibre has reached such a tube it can, following the direction of gravity, grow on in the moist air of the passage, without meeting with the least

resistance, and it finds moist, loose, fertile earth in abundance. With regard to the numerical value of this action of the earthworm, the following observations by M. Hensen afford some information.

Two worms were put into a glass pot 1 $\frac{1}{2}$ foot in diameter, which was filled with sand to the height of 1 $\frac{1}{2}$ foot, and the surface covered with a layer of fallen leaves. The worms were quickly at work, and after 1 $\frac{1}{2}$ month many leaves were down 3 inches deep in the tubes; the surface was completely covered with

not proved by any fact; roots gnawed by worms were never met with, and the contents of the intestine of the worms never included fresh pieces of plants.

The experience of gardeners that the earth-worm injures pot plants may be based on the uncovering or mechanical tearing of the roots.

“Let us take a retrospective glance,” concludes the author, “over the action of the worm in relation to the fertility of the ground. It is clear that no new manure material can be produced by it, but it utilizes that which is present in various ways. 1. It tends to effect a regular distribution of the natural manure material of fields, inasmuch as it removes leaves and loose plants from the force of the wind and fixes them. 2. It accelerates the transformation of this material. 3. It distributes it through the ground. 4. It opens up the undersoil for the plant roots. 5. It makes this fertile. *Nature*.”

Notices of Books.

The Rose Annual for 1877-8. By William Paul (Waltham Cross).

This opens with a review of the season from a rosy point of view: then follows a notice of the new Roses of the new year, and some useful hints on Roses for garden and house decoration, in which the author gives a much-needed hint to those well-meaning enthusiasts who look to "Rose shows" as the *summum bonum*. It is well to remind the devotees that the pleasure of exhibiting or of visiting exhibitions is shared by tens, while that of growing Roses in the garden for the mere pleasure and *délassement* they yield is the valued privilege of thousands. We would not undervalue exhibitions, but there is a tendency to over-rate their importance, and an unconscious tendency on the part of their promoters to depreciate the simpler tastes of those who love flowers for their own sakes, and to pass over as of little worth anything that does not conform to the rigid standard necessary for exhibition purposes. A review of the principal Rose shows of the season follows, and last, under the head of Correspondence, a variety of interest-lag details, especially with reference to the newer seedlings. Prefixed to the pamphlet are coloured figures of Red Dragon (H.P.), Rosy Morn (H.P.), Perle des Jardins (Tea), and Magna Charta.

The Diet Cure. By T. L. Nichols, M.D.
429, Oxford Street.

There is a good deal of sound common-sense in this little pamphlet, inculcating pure air, pure water, strict personal cleanliness, moderate diet of bread, fruit, vegetables, without meat or fermented liquors, sufficient clothing, occupation for mind and body, alternating with periods of rest and recreation. There is, however, too much advertisement of Dr. Nichols, his books, his "food," and his doings generally, to command confidence; and while his teaching is generally sound, he sometimes runs into extremes, as in his denunciation of meat as food, and in his exaggerated statements as to the effect of his system of dietary in various diseases, not even excluding cancer. Such statements can only do harm. Once certain main principles well grasped—a man, as it is said, is as regards himself either a fool or a physician at forty—and he is in general wise enough to see that what may suit him may not suit his neighbour. "What is one man's meat is another man's poison."

The Villa Garden.

WINTERING DAHLIA ROOTS.—"What shall I do with my Dahlia roots during winter?" asked a Villa gardener a few days ago. He had grown a few during the summer in a side border, and, being previously somewhat imperfectly acquainted with the flower, was much pleased with the result. The plants were put out in some rich soil the second week in June, they were well attended to in the way of mulching, watering, and tying; and the moist season helped the plants wonderfully, and a capital head of bloom resulted in the case of each plant. Up till quite lately the plants were loaded with these flowers, then came a bright starlight night, accompanied by a sharp frost, and the next day all were a blackened rotting mass. Soon after the stalks were cut away within 2 feet of the ground, a fork inserted under the roots and lifted 2 or 3 inches; the result was that the fibres were loosened in the soil, and a space was

created under the roots into which the drenching rains could pass, leaving the soil about the tubers comparatively dry.

HOW TO STORE.—A fortnight ago the roots were lifted with some soil adhering to them and put into an outhouse to dry a little; the remaining stalk was cut down to within 6 inches of the roots. When they were sufficiently dry the question arose, where best to store them away for the winter? This has puzzled many a gardener whose love for certain flowers was far greater than the means at his disposal for storing away certain pet subjects during winter. Therefore we have heard of many expedients being resorted to for wintering Dahlia roots, even to that of putting the roots into paper bags, with a little soil about them, and hanging them up in the kitchen or living-room. A Dahlia root will bear a good deal of drying, at the same time it is best to keep the tubers as plump as possible. A hot dry position is hardly to be commended; it should be dry and cool at the same time, and if exposed to the action of frost, why it is a simple matter to apply some covering when the weather is severe. Hundreds of shifts have to be resorted to by amateur gardeners in order to preserve their treasures alive and unharmed during the winter.

One Villa gardener has constructed a rude kind of shelf in his outhouse, on one of the side walls near the roof. On this he has spread some soft hay, and there he has placed his roots. Light and air are given by day, and should it happen that sharp weather sets in some more hay will be placed snugly about the roots and tucked in well about them, and the additional protection of a piece of old carpet or a garden mat afforded. No harm will be permitted to come to them, they are too highly prized to needlessly expose them to any risk. During the winter the roots will be looked over to prevent decay, or to arrest its progress if it appears.

HOW TO WINTER THE PLANTS.—This expedient, and it can lay no claim to novelty, suggests how many plants of a semi-hardy character may be kept through the winter where there is an entire absence of glass. Supposing any one has grown a few favourite Fuchsias, Lobelias, Calceolarias, Pelargoniums, Lantanas, succulents, and such other plants as are employed in the summer garden which they may be desirous of preserving through the winter, the expedient of a shelf in an outhouse suggests the means by which it may be done. Last winter some succulent plants were lifted from the flower-beds in October, and planted in shallow wooden boxes with some cocoa-nut fibre about the balls of soil, and put on a shelf in a warm outhouse where some light could fall upon them. As Echeverias, Sempervivums, Pachyphytums, Kleinias, and such-like are slow-growing plants, it is all the more important to save them through the winter, especially on the part of any one who makes a little speciality in the way of a succulent bed: for while Pelargoniums, Calceolarias, Verbenas, Lobelias, &c., are plants of quick growth, succulent plants require time to grow into size.

Our experience teaches us that any specimen plants lifted from the open ground winter best in soil rather than cocoa-nut fibre or any such substitute. Our advice to Villa gardeners is to put all such plants in a soil similar to that obtained from a potting bench, having the pots well drained, and not lifting too much soil with the roots. The method recommended by some of trimming the roots is right enough when the plants are to be put into some warmth in order to excite them to growth; but when they are to have cold treatment we have found it best to leave the long roots intact, and to place them as far as possible immediately round and in contact with the pots; for they put forth spongioles at their points, which has a valuable rallying effect on the plants. If the soil be used nicely moist, but not to the degree of stickiness, potting is a pleasant process, and it will not require water for some time unless brought into contact with drying influences.

TREATMENT DURING FROSTY WEATHER.—When there is the appearance of frosty weather setting in, the plants should be allowed to become quite dry, and then danger from that cause is much lessened. If the enthusiasm of an amateur gardener who is just feeling his way in the matter of cultivating plants may be said to overflow in any one direction it is that of use of the watering-pot. He is ever asking for signs when a plant is dry, and it is very difficult indeed to

educate him up to this point. If some newspapers be placed over and below the plants, placing thicker folds as the frosty weather to be guarded against increases in intensity, its insidious advances will be checked and harm kept at a distance.

Directly the spell of frost has broken up let the plants be uncovered and examined. They should not be kept in total darkness a moment longer than is necessary. Cut away any decaying parts of the soft points of the branches, remove any withering leaves, for they are so many avenues by which damp may find its way to the stems; and if the weather happens to be soft and balmy, as it is sometimes after a thaw, the plants may be stood out in the sun during the day and a little water be given to them. It is a little attention that saves so many plants; a constant alertness and supervision override many difficulties, and the way to substantial reward is never reached through the byways of careless inactivity.

Garden Operations.

PLANT HOUSES.

Spring and summer-blooming hard-wooded stove plants, if treated as from time to time advised, will now be in a state of rest, especially such as are of a deciduous nature. Where there is only one stove in which to have the plants in this condition, along with others that require through the winter to be kept slightly moving, as well as the numerous things that are wanted to be pushed along for present and successional blooming, it becomes a somewhat difficult matter to treat all according to their requirements; but much may be effected towards the end required by regulating the water supply to the roots for the deciduous or partially deciduous section here, such as Allamandas, Dipladenias, and others of similar habit, can be kept from making growth, even when the temperature is sufficiently high to excite it through keeping quite dry, which will have no injurious effects upon plants of this description, to still further assist which they should occupy the end furthest away from the boiler, which will generally be several degrees cooler than the opposite; and to further increase the difference in temperature, all the air that is admitted should be given at the coolest end. Such plants as the above will, by gradually withholding water as advised until the leaves have flagged, have got into a dormant condition, first, through the cessation of root growth, with accompanying little or no extension of shoots, and be in a condition to well bear the soil getting so dry as above recommended. I have found this treatment much better than drying up the atmosphere of the stove by withholding water from the evaporating troughs altogether, or ceasing to throw any upon the floor and side stages, as where the latter is resorted to it has a most injurious effect not only upon the winter blooming subjects, but also on all evergreen plants, such as Ixoras, Gardenias, and the like. When the atmosphere is as dry as it used at one time to be almost general to submit stove plants to through the winter, the leaves of evergreen subjects always suffered to an extent that brought about a stagnant condition, which it was difficult to get them out of in spring. If not already done, one or two Dipladenias should be cut back. This is necessary where the plants are required either for the production of early flowers for cut purposes or for exhibition; in the case of full-sized specimens the knife may be used freely, shortening the shoots to within a foot or 15 inches of where they were cut back the preceding year. This is much better than allowing an unnecessary length of old shoots, as, however long they are left, there is seldom a disposition to break more than two or three to each. As to potting I have followed different courses, either letting the plants break before the partial shaking-out, which it is necessary to subject them to after cutting-in, or to re-pot immediately they are cut back, and I find the latter method much preferable, for although they break somewhat weaker consequent upon the disturbance and considerable breakage of the smaller roots, still there is no after-check, such as occurs when the potting is deferred until the plants have broke, and which generally stops a portion of the young growths from extending further at all. To grow Dipladenias, which are amongst the most useful of all stove plants, in a satisfactory manner, they must have the soil renewed once a year, no matter how fit for lasting longer the old material may appear at the present time, or the chances are that before the next season is over it becomes too far decomposed and sodden for the roots to move freely in. Peat I find much better than loam for these plants, where it can be had of a thoroughly fibrous description. If this is not obtainable I should advise the use of turfy loam, working all the earthy particles out through a sieve, and employing little besides the roots of the grass and herb-

age which good loam contains; it is essential to add plenty of sand to whichever is used, peat or loam. Clerodendrons that bloomed late will now be making growth, and must be encouraged by a sufficient supply of moisture at the roots, keeping the shoots regularly trained as near the roof-glass as possible without absolutely touching it. Shrubby Clerodendrons, such as *fallax*, *Kempferii*, and the finely-scented *C. fragrans*, may now be cut-back and allowed to break slowly. So treated they will bloom a month or six weeks earlier than when the operation is deferred eight or ten weeks later. Where these shrubby Clerodendrons are grown from seed sown in the summer, they make fine decorative subjects grown on single stems, kept on moving freely all through the winter. Plants from seed sown about the above time will, if all has gone well, be now in 6-inch pots, and if these are well filled with roots they should be moved into others a couple of inches larger, using good open soil and keeping the plants close to the glass, otherwise they are liable to get too tall. The earliest portion of the winter blooming stock of *Euphorbia jacquiniiflora*, *Poinsettias*, *Plumbago rosea*, *Thyrsacanthus rutilans*, *Eranthemum pulchellum*, *Sericographis Ghiesbreghtii*, and the ever blooming *Scutellaria Mocciniana*, must be kept tolerably warm—from 65° to 70° in the night, with a corresponding rise in the daytime; and the plants with their heads close to the glass will bring them on in a way that will give enough substance and solidity to the flowers to make them stand well when cut. *T. Baines*.

ORCHIDS.—The natural cessation of growth now observable among many of these plants, which is perhaps more decided and noticeable in the *Dendrobium* section and those that are of a deciduous nature, coupled also with the fact that the small amount of sun-heat that is now obtainable, makes it necessary to adopt means and methods of treatment so that the natural tendencies of the plants may fall in with such a course and be benefited by it. The state and condition of the atmosphere in the houses as regards moisture must now be very different to that which we required during the summer season. Then, during parts of the day intense humidity had to be maintained. Now, however, the moisture must be considerably less, therefore all damping-round should be done after the temperature has commenced to rise in the morning, and if further damping is required it should be done not later than 2 o'clock in the afternoon, so that any excess of moisture may have been partly dried up or absorbed, and no fear of damp or heavy drip likely to occur during the night. On this point it must be borne in mind that a paved or tiled-covered floor will require more water being thrown about it than one where the paths are made of wooden lattice-work, and where also the spaces under the side stages are all of an earthy nature, Ferns and moss being probably planted in them. In this case the evaporation is so much slower, on account of the quantity of water held by or contained in the soil, that a good damping in the morning at this time of the year will in many cases be found to be sufficient, yet, since all houses are not built alike, it will be necessary to work according to the means and circumstances that are at command. Lower the night temperatures to the following numbers, using, however, a little latitude as the temperature outside is higher or lower. When much fire-heat is necessary keep as near as possible to the lower numbers, when the air out-of-doors is mild and genial the higher ones may be reached occasionally without injury. East India-house, 60° to 65°; *Dendrobium* house, 55° to 60°; *Cattleya* house, 55° to 58°; *Odontoglossum* house, 50° to 53°. Plants on blocks, more especially those that are hung over the stages, should now be taken down and dipped, and the water be allowed to drain away from them before they are hung again in their places; only dip those that really require watering. Some of the most forward plants of *Dendrobium nobile* must now be brought from the cooler structures in which they have been kept at rest, and placed in the *Dendrobium* house; here at first they will not need any water, but as the buds push out and the flowers are perfected, a regular supply will have to be given, but then only enough to support the blooms and keep the bulbs from shrivelling. The later and larger plants of this old favourite, as the growths are formed and ripened, must be stood for a couple of months at least, and longer if necessary, in a cooler division, so that by this rest and absence of exciting inducements to start into growth they too may set their flower-buds for the coming spring. As the *Calanthes* come into flower they should be stood among the other plants, the loss of leaves, in which condition they flower as a rule, is not so apparent as when flowering a lot together; keep the flowers free from damp, and let no syringings fall upon them, otherwise the beauty and freshness of the blooms quickly disappear, causing much disappointment and regret. *C. Veitchii* and its varieties will now be very showy and doubtless very plentiful, for it grows and increases very freely. Amongst the *vestita* section the yellow eyed variety and rich bronze cupreum are two that

should be more generally grown than would appear to be the case. *W. Swan, Fallowfield*.

FLOWER GARDEN, ETC.

Since the gales of wind and heavy fall of rain which we have lately had the trees are now nearly stripped of their foliage, only a few remaining on some of the Oaks. A general cleaning of the shrubberies and pleasure-grounds may be commenced as soon as the weather is somewhat settled, removing dead branches from any of the trees or shrubs as the work proceeds. Any transplanted trees that are likely to be exposed to the influence of the wind had better have supports to keep them steady in their places. This is favourable weather for lifting and planting trees and shrubs of all kinds, and if the planting is carried out with due care, and the plants that are removed not over large, and a little water given to settle the earth about the roots, very few failures will follow the operation. I have no faith in saturating the soil as I have sometimes seen done. Where planting is required for immediate effect and future satisfaction, the ground should be trenched or double dug. This causes a little more labour at the commencement in preparing the ground, but the planting is easier and better performed, and the plants do not require so much attention afterwards, but in a great measure are able to take care of themselves. The lawns, after so much rain, begin to get soft and spongy, worms are also getting troublesome, but sweeping and frequent rolling will soon restore them to their desired form, and leave them clean and enjoyable. Plants and trees in exposed places will require looking to, that the ties and fastenings may be secured where they have become loose. Wherever weeds show themselves on walks they should be handpicked or get a sprinkling of salt, which will soon stop their further progress for the season. The flower-beds are now all cleared of their summer occupants, and where not wanted for a display of spring flowers will be much improved by a good dressing from the reserve heap, and if a little fresh loam can be added it will further assist them. Trenching the beds will bring fresh soil to the surface, and enable the plants to stand the dry weather of summer without requiring much water, which is better for the plants and a saving of much unnecessary labour. *T. Blair, Shrubland Park*.

FRUIT HOUSES.

VINES.—Where the earliest Grapes are obtained from pot Vines, those which were introduced about the first of the month will now be on the move, and sufficiently advanced for the introduction of fermenting materials, which will greatly facilitate forcing, while it reduces the necessity for continuous firing. If the pots have to be raised any distance from the bottom of the pit they should be placed on solid pedestals, or, what is better, in long troughs formed by nailing three boards together. After enlarging the holes at the bottoms of the pots tilt them on a thin layer of drainage, and place a small quantity of rich turf and bones round them for the reception of the roots which will soon begin to emerge from their confinement in search of food. Gradually increase the supply of compost as the roots advance, and feed when the proper time arrives. By the adoption of this plan the fermenting material may be turned and renovated at will without disturbing the pots or roots. Assuming that all border work in the way of additions, lifting, and top-dressing has been brought to a close, as in every case it ought to be before the leaves fall, the pruning of mid-season and autumn houses may be proceeded with as soon as the foliage parts freely from the young wood. If all Vines were divested of lateral and extension growths as soon as the last bunch is cut and pruned in November, styptics would not be required, wounds would heal thoroughly, and plump buds at the base of every shoot would produce close handsome clusters, instead of loose bunches, which never give pleasure to practical gardeners although they sometimes captivate the theorist. If not already done go carefully over the latest houses. Remove all laterals and extension growths, as they do positive harm by keeping the Vines excited when they ought to be at rest. Clear away all ripe foliage as it falls, and cover the inside borders with some dry nonconducting material, which will keep down ground moisture and prevent the surface-roots from getting too dry as the winter advances. Clean dry bracken is suitable, looks well, and improves the appearance of black Grapes. The heavy rain of the past week having thoroughly saturated the earth and atmosphere, bunches of Hamburgs and other thin-skinned Grapes will now keep better in the dry equable temperature of the Grape-room than on the Vines. Cover up outside borders, early and late houses with shutters or lights, and mid-season houses with Fern or litter, for keeping out frost. Have a good supply of thoroughly worked and sweetened Oak leaves and short stable manure always in readiness for inside, and for covering up outside borders of early houses after, but not before, the Vines are started. *W. Coleman, Eastnor*.

HARDY FRUIT GARDEN.

The severe frost that occurred on the night of the 18th of last month and the strong winds that followed have stripped trees of their leaves much earlier than usual, but owing to the wood being so thoroughly mature there is fortunately some advantage in this, as it affords an opportunity that should not be lost for pushing forward planting operations while the soil is still warm and in excellent condition for carrying out the work. As many may be at a loss, from the vast numbers of varieties there are of most kinds of fruits, which to choose, it may be well to enumerate a few of the best sorts of each that will keep up a regular succession so long as they last in season, and are of that hardy nature that they will be found satisfactory in most districts. To begin with Pears, there are a very quantity of these that ripen early, and more particularly is this the case from October to Christmas, a season when most of the best are in use, and from which those named below are the cream. The first and most luscious of what ripen in July is the old Jargonelle, a Pear that when grown in an open sunny position is still unrivalled, but in order to enjoy its full flavour it should be eaten almost as soon as it is plucked from the tree. The next in merit to come in about the same time is *Beurré Giffard*, a handsome fruit, and one that bears well on the Pear stock if planted in good soil in a fully exposed situation. To come in at the end of August, *Williams' Bon Chrétien* is the handsomest and best, but as they ripen quickly after being gathered a portion only of the crop should be got at one time, and the picking continued at intervals of a few days. During September there are so many good sorts that it is difficult to confine one's selection to the limited number of two or three, but excellent as the several varieties are that are then fit for table, the following are decidedly the richest and best. *Beurré d'Amanlis* is not only large and handsome but is exceedingly rich and buttery, a strong grower and a good bearer, although a little too straggling in its habit to form a fine pyramid. Another Pear of quite equal merit to the foregoing is *Beurré Superfin*, which on the Pear stock grows vigorously, and is very hardy and productive and suitable for almost any soil or situation. To succeed these there are none equal to *Louise Bonne*, a pear that should not be omitted even in the most limited collection, and if only one can be grown this will be found the most useful as it rarely fails to bear good crops, and the fruit is always delicious. For October, the Pear of all others is the *Marie Louise*, which from the long straggling nature of its spurs does best as an espalier or on a south-west wall where it can have support and not be too closely pruned. In warm favourable districts, and on a south wall, *Duchesse d'Angoulême* will be found a grand Pear, but unless it can be so accommodated it is useless attempting it, as it comes gritty and without that rich perfume and good quality they possess when ripened in a good climate. To the *Marie Louise*, however, should be added *Doyenné du Comice*, a Pear that cannot fail to give satisfaction. To come in from October to Christmas, *Pitmaston Duchess*, *Passe Colmar*, and *Glou Morceau*, are the best, that should be afforded a wall having a south-west or south-east aspect. After Christmas, *Josephine de Malines* and *Bergamotte Esperen* will continue the season as long as Pears will keep, and are the only two late kinds that can be depended on to finish off well. For cooking purposes there are none to equal *Catillac* and the *Brown Worcester*, except perhaps *Uvedale's St. Germain*, which is worth growing, owing to its fine size and productiveness. Space will only permit of me just naming the best Apples, the first of which to come in use for dessert is the *Kerry Pippin*, and for culinary purposes *Keswick Codlin* and *Lord Suffield*. To succeed these, *Ribston Pippin*, *Blenheim Orange*, and *Cox's Orange Pippin* are the best both for dessert and kitchen use, as the flavour is richer than any of the others, and they require but little if any sugar. For late use there are none better than *Herefordshire Pearmain*, *Court Pendu-plat*, *Claygate Pearmain*, *Dumelow's Seedling*, *Winter Majetin*, *Yorkshire Greening*, and *Sturmer Pippin*. The best and most distinct Plums for dessert to grow on walls are the *Green Gage*, *Kirke's*, *Jefferson*, *Reine Claude Violette*, *Reine Claude de Bayay*, and *Coe's Golden Drop*, which ripen in the order they are placed. For culinary purposes, to grow as standards, *Prince Engelbert*, *Prince of Wales*, and *Victoria* are the best and most productive, the latter so much so that the branches frequently get broken off by the great weight of fruit unless they are thinned or have some support afforded them. In Cherries the *Black Eagle* is the earliest and best, to be followed by *Frogmore Bigarreau*, *Tartarian*, and *Elton*, for dessert; and for cooking there is none equal to the old *May Duke*, the subacid flavour of which is highly esteemed. Although it may be desirable in some gardens to add to the above list of fruits, as regards Apples and Pears it is sufficiently complete for the majority of places, and it will be found more satisfactory to grow several trees of one kind than to greatly increase the number of varieties. *T. Sheppard*.

THURSDAY, Nov. 22	{ Leeds Chrysanthemum and Winter Flower Show (two days). Cheetham Hill and Crumpsall Floral and Horticultural Society's Show.
FRIDAY, Nov. 23	{ Sale of Hardy Plants and Bulbs, at Stevens' Rooms.
SATURDAY, Nov. 24	{

THE rearrangement of the HEATING APPARATUS in the PALM-HOUSE of the Royal Gardens, KEW, is a work of such magnitude and importance that we are glad to have the opportunity of laying some account of it, together with a plan of the boilers, before our readers. For the opportunity of doing this we must express our acknowledgments to Mr. E. G. RIVERS, C.E., the patentee of the new boilers, and to Mr. SMITH, the Curator, who allowed us to inspect the apparatus when in action. Last winter and spring Mr. SMITH had to contend, as our columns showed at the time, with unusual difficulties from the filling of the stokeholes and the basement generally with water. For months two steam fire-engines, supplemented by manual labour, were engaged in pumping out the water. From the first the stokeholes had been ill-constructed dens, difficult of access, and something worse than inconvenient when entered. The heating arrangements, moreover, were such that peace of mind for the Curator and his assistants in a hard frost was not to be had. The old boilers, eleven in number, each 5 feet in length, had a total fire-grate area of 79 square feet. Eight of these boilers were ordinarily in use in moderately severe winters, the whole eleven whenever the weather was rigorous. But one main cause for the uneasiness we have alluded to was that the boilers were separate and distinct, with no means of intercommunication, so that if one failed, the section of the stove dependent on that one suffered, or was liable to suffer, accordingly. To remedy this state of things a new system of heating has been adopted; the stokeholes have, under the direction of Mr. JOHN LESSELS (District Surveyor to Her Majesty's Office of Works), been made light, convenient, we had almost said luxurious. Impervious floors of puddled clay and concrete, extending partly along the tunnels which communicate with the smoke-shaft, coke-yards, &c., have been constructed, so that in conjunction with other arrangements which need not here be mentioned, it is to be confidently expected that the plague of waters will no longer harass the Curator. These stokeholes suggest the idea of some vast cathedral crypt, with the difference that these are light, warm and clean—qualities not always observable in ecclesiastical substructures. The opportunity has also been seized of conveying pipes round the gallery, with a view to check the condensation and drip, which was so detrimental to the foliage of the Palms.

The boiler devised by Mr. RIVERS may briefly be described as a tubular saddle, the tubes being 7 feet in length, of this shape , the upper portion forming the flow, the lower the return. The tubes, which can readily be removed for repairs, are constructed of wrought-iron, and arranged horizontally in horse-shoe

shape. They pass through a cast-iron case or chamber, the communication with which is established by means of slots. There is now one universal flow and return system, the main pipes being 10 inches in diameter. All the boilers can be used if necessary simultaneously, though as a rule three, or at most four, will be all that will be required in severe winters, the others being available in case of accident. When we saw the apparatus in action on a mild autumn day, somewhere about $3\frac{1}{2}$ miles of piping were in use heated by three boilers, the main pipes being arranged across the house, the smaller ones branching from it lengthwise. The return tubes of the boilers, though next the fire, were perceptibly the coolest, although all, or at least the lower ones, were so near the fire that the first impression created was that after a time the circulation would cease, but a perusal of the following details will show how this is obviated, and thorough circulation ensured.

The new boilers are six in number (each 7 feet in length), with a total fire-grate area of 54 square feet. It is evident, therefore, that the saving in fuel will be considerable, as the maximum fire-grate area in use at one time will be 36 square feet as against 79 square feet of the old system.

The total quantity of pipe in the Palm-house is, we learn, equal to 19,510 feet of 4-inch pipe, or 4877 feet to each boiler (supposing four to be used), and by the improvements recently effected the whole system is, as we have said, united by the main flow and return pipes into which all the boilers work. The whole of the engineering works have been executed in a most satisfactory manner by Messrs. SIMPSON & CO., of Pimlico.

As regards improvement in the construction of hot-water boilers, but little progress has been made during the last few years; in fact, it would seem that the designers of some of the boilers recently introduced have not acted in accordance with the principles which govern the circulation of hot water, and also of the conditions under which boilers of this description are worked.

One serious defect is the large capacity which is given to many of the patterns. The object in view is to heat the incoming water as rapidly as possible, and to pass it away to its work with equal rapidity. The inlet is generally a 4-inch or a 6-inch pipe, and the outlet the same; therefore, any increase in the capacity of the boiler beyond the size necessary for the supply of a 4-inch or a 6-inch pipe at the maximum rate of flow (with due regard to adequate heating surface), results in waste of fuel uselessly expended in heating the contents. The important fact to be borne in mind is, that the whole apparatus forms the boiler, and we only have to deal with that portion of it which is exposed to the fire when we use the term "boiler."

The next point to which we would invite attention is the fictitious value given to flue-heat. In some of the recent patterns of boilers we find an extremely small area exposed to the direct action of the fire, and a complex series of ramifications beyond, through which the products of combustion are made to pass, and are supposed to impart to the surfaces of the boiler a heat which in reality they themselves do not possess.

The result of frequently testing the temperature in the flues of various patterns of boilers shows that except during very rapid firing the heat from the first return of the fire (which is, of course, the most effective) has an average value of only one-fourth as compared with the direct heat of the furnace.

Hot-water boilers are generally worked with a slow draught, and in the majority of cases get comparatively little attention, hence it is

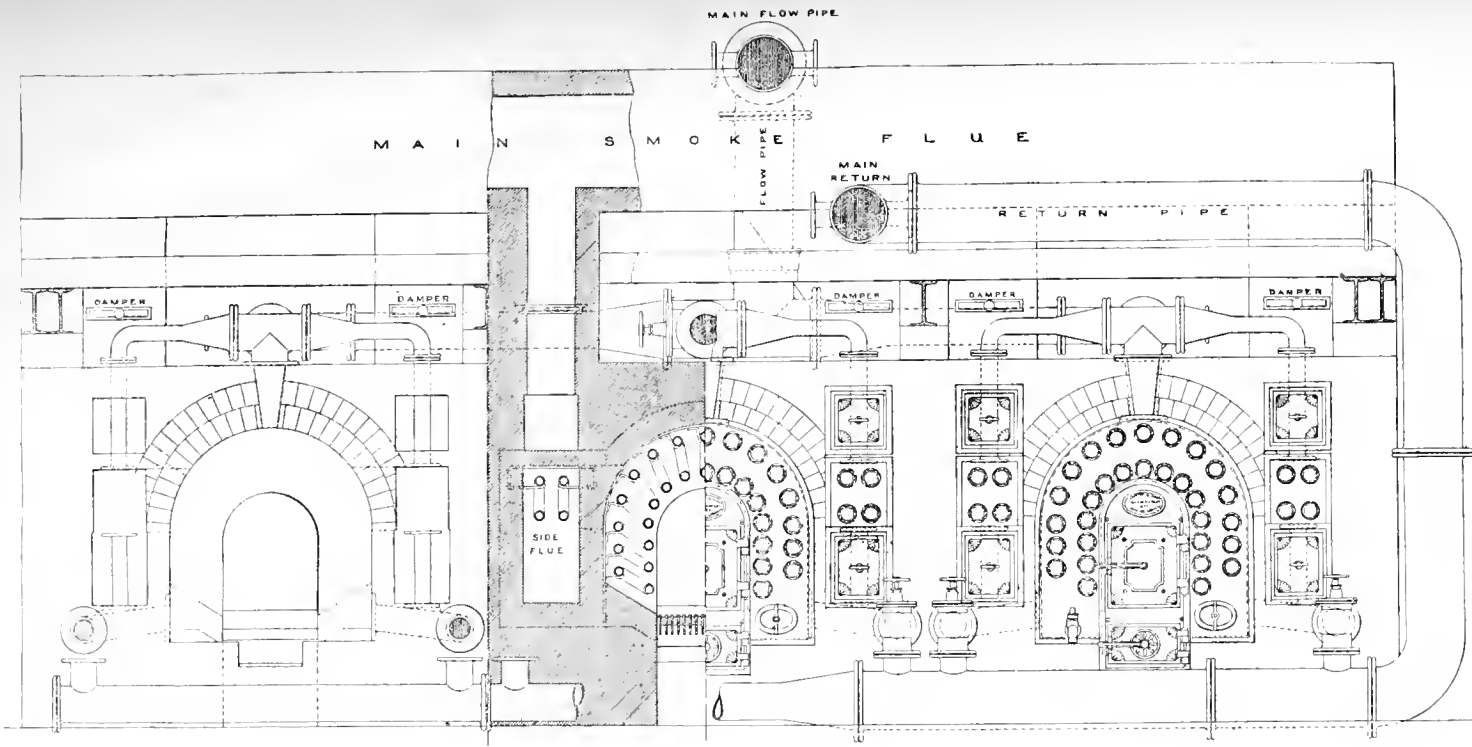

important to secure a large surface exposed to direct heat, and as coke is the fuel most generally used, little or no flame passes into the flues. Unless frequently swept the value of flue-heat is further decreased by the deposit of soot which rapidly forms a coating upon the surfaces of the boiler, and acts as a non-conductor.

We now come to the last, but not least, important defect, *i.e.*, the difficulty and in many cases the impossibility of effecting repairs. A boiler capable of heating 3000 or 4000 feet of pipe is an expensive article, and as the parts liable to be burnt through are those in close proximity to the fire, it will readily be seen that any improvement in construction which enables the most exposed parts to be repaired or removed without sacrificing the entire boiler must be a great boon. It is also important that the repairs should be effected without removing the brickwork or disconnecting the boiler from the pipes, the delay consequent upon these operations being very serious if, as generally happens, the boiler fails during active work and in cold weather.

The proposed rearrangement of the heating apparatus in the great Palm-house induced Mr. RIVERS to conduct some experiments with a view to designing a boiler possessing great power and rapidity combined with facility of repair, and the result of these convinced him that if the defects which had hitherto been associated with the tubular system could be removed, the large surface exposed to the direct and reverberated heat of the fire by boilers of this description present special advantages. One of the principal defects of the tubular system was the choking of the tubes from deposit of sediment and the generation of steam consequent upon defective circulation. This is obviated in the new boiler by dividing the collecting chamber by a diaphragm, so that the communication between the flow and return tube of each pair necessitates a rapid passage of their contents through the furnace. The particles of deposit will be carried through the tubes, and in returning to the boiler will sink to the lower part of the chamber below the return inlet, and therefore out of the circulation. Proper means are provided for the removal of the deposit when necessary. When, from long use, any tube should leak, it can at once be seen, and after shutting off the valves and emptying the boiler, it can readily be removed by unscrewing the nuts in the front of the case, slipping the tubes back, and removing them through the fire-door. A spare tube can then be substituted, or the apertures in the collecting-chamber can be closed by a plug provided for the purpose, and the boiler set to work, minus the tube, without any appreciable diminution of power. The collecting chamber is not exposed to the action of the fire, and being constructed of metal of unusual thickness, is practically indestructible. The tubes can be as readily renewed as a set of fire-bars, and at a small expense. Supplementary pipes are also placed in the flues, but these are accessories which, as it seems to us, are of very minor importance.

Such are the main features of the improved tubular boiler now in use at Kew. Up to the present time Mr. SMITH has been well satisfied with its performance, and its action during the coming winter will be carefully tested with a view to ascertain its efficiency and the expense in working.

— THE illustration of a portion of the grounds of PIERREMONT PARK SOUTH, DARLINGTON, the residence of HENRY PEASE, Esq., now given (fig. 126), will recall to the attention of our readers the notice of this charming place given by Mr. J. DOWNIE on p. 394 of the *Gardeners' Chronicle* for March 25, 1876. What particularly strikes the visitor is the great amount of detail displayed in such a comparatively small space; and so well has this been accom-

plished, so much artistic skill has been brought to bear on the work, that the grace of natural beauty has never been lost sight of; and, indeed, as time throws its mellowing influence over the gardener's art, the traces of artificial handiwork are gradually melting away into that expression of natural grace to which all art should tend. The foreground of our illustration is from the lower part of the pleasure-grounds. In the distance is Pierremont House, with the Pinetum coming between it and the handsome fountain and basin, with its choice collection of aquatics and circle of handsome Pierremont vases. The lake and its surroundings do much

also been employed in the flower garden, and with the best results. At the end of the lake, on a piece of rising ground, Mr. PEASE has had a charming Swiss cottage erected, which contains an ample and handsome room, of which tourists who come to see Pierremont can avail themselves. One pleasing custom at Pierremont is that respectable persons are permitted to roam about the grounds, and this kind privilege is never abused. In addition to many features of special interest in the grounds, Mr. BARCLAY is in course of forming a collection of the choicer kinds of hardy perennials. A new Peach-house has recently been constructed, and other improvements are to be made as opportunity

past season, it is the great beauty of CROTON WEISMANNI as an exhibition plant. It is a variety of free and vigorous growth, and with handsomely variegated leaves displayed to the best advantage by reason of its peculiar habit. Many large-sized examples have been exhibited, and the general rule has been for them to be finely coloured. It is a distinctly habited form, and will always take high rank for show purposes.

— Messrs. HARRISON & SONS announce that their eighth annual exhibition of farm roots, &c., will take place on November 21 and 22, in the Market

FIG. 126.—VIEW IN THE GROUNDS, PIERREMONT PARK SOUTH, DARLINGTON.

credit to the skill of Mr. BARCLAY, the gardener at Pierremont, who had the execution of the work. The place is admirably kept, and at no season of the year can a visit be paid without seeing much to interest one. During the past summer Mr. BARCLAY introduced some illustrations of carpet-bedding, and notwithstanding the cold and sunless character of the summer tender plants, such as Alternantheras, have done remarkably well, while succulents have flourished amazingly. This is nearly, if not quite one of the first attempts to introduce into this particular district that particular style of gardening which has made Heckfield and other places so famous; it has excited much interest among neighbouring gardeners, and there is reason to believe it will be much followed in the North of England in the coming time. Violas of different shades have

serves. Horticulturists visiting Darlington find a cordial welcome from Mr. BARCLAY, and the liberal proprietor of Pierremont is desirous that the charms of his garden should be appreciated as widely as possible.

— We note in the *Bulletin of the Royal Botanic Society of Belgium* an announcement of the death of Mdlle. HENRIETTA CERF, who was born in Jamaica in 1810, and died in Brussels on the 22d ult. Mdlle. CERF, who for some years resided near Dinant, communicated various articles on the botany of Kent and Belgium to the *Phytologist*.

— If any one special lesson has been taught in connection with horticultural exhibitions during the

Place, Leicester, and the prize roots will be exhibited in the seed warehouse on Saturday, November 24.

— A few days before the close of his year of office, Mr. JOHN KEYNES, late mayor of Salisbury, following the custom usually observed in the city, entertained at dinner the town council, the city members, and a large circle of personal friends, including several members of the horticultural profession, among them Mr. CHARLES TURNER, of Slough. Mr. KEYNES closed his mayoralty amid the good wishes of all, and with fervent hopes that he may be spared to a life of usefulness for years to come. Horticulturists are not slow to take upon themselves the duties and responsibilities of citizenship; and in the course of the recent municipal

elections up and down the country it has been noticed that many members of the profession have been elected to councils, and the higher duties connected therewith.

— At a recent meeting of the committee of the INTERNATIONAL POTATO EXHIBITION, the accounts for the past year were presented, showing a small balance in hand after the satisfaction of all liabilities. A sub-committee was appointed to consider the best places in which the exhibition of 1878 could be held. It was suggested that the exhibition next year should take place a little earlier than usual, to allow of the committee making a collection of the best tubers shown at the annual show, and sending the same to the Paris Exhibition as a contribution from the International Potato Exhibition. This found much favour, and it will be fully considered at an early meeting of the committee. Could not a representative collection of fruit be got up in the same way?

— Are we to have the HARD WINTER so freely prophesied, or shall we have a repetition of the soft, moist weather that prevailed last winter? These are questions that sadly trouble the minds of gardeners, because in either case no pleasant prospect is afforded. Perhaps a middle course may be steered and a period of moderate cold and frost with a fair portion of fine open weather may result, but it is an unfortunate fact that we have recently experienced weather almost exactly corresponding with that which heralded the previous moist winter—the winter of downpours and floods, of south-westerly winds and muddy, oozy days; indeed, in these respects a most disastrous winter for all. We had a very delightful dry October, truly a glorious month in spite of some storms and tempests, but its successor is wild and wet and well maintaining its old reputation as being one of the most miserable months of the year. Yet it is comparatively mild, and under the influence of a low temperature, plenty of moisture, and a few comparatively sunny days, the earlier spring flowers are blooming freely, and give us a taste of that yet far off time when the new year shall once more open to us Nature's storehouse of floral beauty. Spring stretches out its hand across the dark chasm of an uncertain winter and grasps that of the fast-receding autumn as though it would indicate that the continuity of life and beauty in Nature is not dead but for a time only sleepeth, and will presently awaken into renewed energy and vigour. Amidst all the uncertainties and vicissitudes of the season gardeners are busy, and pushing on with all possible despatch the needful work. Gardening must never stand still, it has to provide for the wants of months and even years hence; and so imbued are the workers of horticulture with the necessity to be ever prepared for futurity, that even the possible knowledge of the near approach of the crack of doom would not stay their hands. Gardening essentially inculcates the maxim, to plant and sow that we may reap and gather fruits.

— Mr. EDWARD GANDY has lately been appointed to succeed Mr. ROBERT CHURCHER as head gardener to the Earl of NORTHBROOK at Stratton, Micheldever, Hants.

— MICROCACHRYS TETRAGONA is quite a gem among Conifers. It is the Strawberry-fruited Cypress of Tasmania, in which country it is common on the western mountains, and on the hills of Port Cypress, forming a prostrate evergreen shrub. A female plant is just now very pretty indeed in the Temperate-house at Kew, nearly every one of the multitude of little branchlets being terminated by a bright red, almost globular, fleshy cone, measuring about one-fourth of an inch from base to apex. By training up a leader the lateral branches arrange themselves in a drooping manner round about. The leaves are ovate, extremely small, in four rows and closely imbricated, deep green in colour. It appears to be rare, no doubt from its being, unfortunately, not quite hardy. A male plant is also to be seen at Kew.

— Among many other NEW FERNS at Kew we are pleased to note a fine form of *Adiantum cuneatum* under the name *Lawsoni*, which, according to many, is of superior merit for horticultural purposes. Botanically it is inseparable from the above species, and, without doubt, is a seedling from it, differing chiefly in the more sharply wedge-shaped divi-

sions, and in their being more deeply lobed. For garden purposes it is abundantly distinct, and immediately strikes the eye of a cultivator, many of whom have anxiously waited its distribution. The fronds, while graceful and elegant, are so thinly composed that in a floral arrangement the flowers are relieved without being in the least obscured—a feature for which *A. gracillimum* is so famous. In comparison it appears to have greater substance, and should therefore be more durable. It is named in compliment to the Rev. W. L. LAWSON, of Lynton, who contributed the plant to Kew.

— In the last volume of the *Proceedings of the New Zealand Institute*, Messrs. KIRK and BUCHANAN describe a considerable number of NEW PLANTS RECENTLY DISCOVERED IN NEW ZEALAND, amongst other things a *Pilularia* and two *Veronicas*. The latter genus is represented by a multitude of forms in New Zealand, many of them very curious and beautiful, and sufficiently hardy to thrive in the south-western parts of the United Kingdom. One of the species described, *V. canescens*, is a delicate little plant with stems 1 inch to 2 inches in length, and leaves from one-twelfth to one-sixteenth of an inch long, and it is one of the most minute flowering plants known, not unlike *Anagallis tenella* in habit. It is the only New Zealand species having solitary axillary flowers. Already between forty and fifty New Zealand species of this genus are known. The ornamental species of *Panax*—*P. crassifolium* and *P. longissimum*—are figured, and their distinguishing characters defined. These plants present such differences in foliage in different stages of growth, that it is very difficult to refer young plants to their proper species. The leaves of *P. crassifolium* on young plants are five-foliate or simple, very coriaceous and stiff, deflexed, 12 inches to 18 inches long, by about an inch broad, distantly deeply sinuate-dentate, purplish below, and dark green above, with a pale green spot on each tooth. Those on the fruiting branches are quite entire, and only 4 inches or 5 inches long, and the flowers are subracemose. *P. longissimum* has very long, distantly-toothed, simple leaves, with a flat margin, whilst those on the flowering branches are more closely toothed, and the flowers are in compound umbels.

— Mr. R. J. LYNCH communicates to the last number of the *Journal of the Linnean Society*, a communication relating to the spontaneous MOVEMENTS in the leaflets of *AVERRHOA BILIMBI*. The movement is one of slow depression, followed by still slower erection. The movement is not spasmodic, as in *Desmodium gyrans*, but is perfectly steady and continuous up to completion. In addition the plant is subject to "the condition of sleep, and is sensitive to mechanical irritation, thus possessing three distinct kinds of movement."

— The BAMIA COTTON OF EGYPT, to which we drew attention at p. 561, vol. vii. of the *Gardeners' Chronicle*, seemed after the subsidence of the first great excitement in its favour destined to pass into the oblivion which is so often the fate of many newly introduced products. Our contemporary, *Cotton*, however, draws attention to the fact of recent experiments that have been made in its cultivation in Texas. The seeds were planted on May 4, in a garden situated in lat. 29° 40', at an elevation of 30 feet above Galveston Bay, and about 300 yards from its margin. The soil was a light, fertile, sandy loam. The seeds germinated, and the plants made their appearance above the surface of the soil in six days, namely, on May 10. The first blossoms appeared on July 8, and the first open fruits on August 30. The average height of the plants was about 8 feet, but some grew up to 10 feet. After the plants had ceased growing the fruits perfected themselves, increasing in size. It is stated that the fruits are very abundantly produced from near the base of the plant to its very top. In the space of four months and ten days from the time of planting, the open fruits were of sufficient size for picking in any quantity. From as careful and safe an estimate as could be made the yield was found to be fully equal to 2500 lb. of cotton in the seed per acre. The habit of the plant is described as being very singular in its outline. Unlike the American Upland and Sea Island cottons it does not send off branches regularly from near the ground to the top of the plant; but the main stem bears close to the

ground two, three, or more branches, and then rises to a height of 8 or 10 feet without a branch. Leaves only are given off along the stems, and in the axil of each leaf are from two to five, and sometimes six, long petioles each bearing a fruit. The branches described at the base were also very heavily fruited, as many as five large fruits growing so close together as to touch each other. The cotton or wool contained in every fruit on the plantation was of a pale yellow colour, which was difficult to be accounted for as there had been no heavy rains during its growth to stain it; it is suggested the profuse dews may have been the cause. From the record of these experiments, it seems that we may still hear something favourable about *Bamia* cotton with regard to its becoming an article of commerce.

— At the evening meeting of the Society of Arts, to be held on December 12, Mr. J. B. LAWES, F.R.S., will read a paper on "Freedom in the Growth and Sale of the Crops of the Farm, considered in its bearings upon the interests of Land-owners and Tenant-farmers."

— Mr. JOHN CROOK, late gardener to T. BOND, Esq., Tyenham House, Warham, Dorset, is appointed gardener to W. SHERWIN, Esq., The Grange, Farnborough, Hants.

— Among the new vegetables being announced in catalogues, M. ERNEST BENARY offers a GOLDEN-YELLOW OLIVE-SHAPED RADISH for summer use. It is described as of a pretty oval form, intense dark yellow in colour, of particularly fine flavour, and very early and adapted for forcing in the open ground. Will this yellow Radish find favour in London markets, where yellow-fleshed Turnips, and even those with colour on the skin, such as the Greentop and the Tipstone, find but little acknowledgment?

— In consequence of proposed building operations necessitating the clearing of part of the nursery grounds at Inverleith Row, Edinburgh, belonging to the LAWSON SEED AND NURSERY CO., a sale by auction of a large portion of the stock of hothouse, greenhouse, and ornamental plants, evergreen trees, shrubs, &c., took place on the 7th and 8th inst. There was a large attendance, including buyers from various parts of England, Ireland, and Scotland; and we understand that there was a great demand for the stove and other plants, which realised high prices; while the nursery and other stock generally sold remarkably well.

— M. WIESNER, in some researches on the TRANSPARATION OF PLANTS, published in *Annales des Sciences Naturelles*, 1877, p. 175, comes to the following conclusions as to the influence of light on transpiration. The functions of chlorophyll in transpiration are evident. Part of the light which traverses the chlorophyll is transformed into heat, as a consequence of which there results a rise of temperature in the tissues, which causes an increased tension in the watery vapour in the intercellular passages. The excess of vapour escapes by means of the stomata. A plant may transpire in a saturated atmosphere, but only under the influence of light. M. WIESNER has studied the transpiration in three different ways. 1. By comparing that of green plants with that of blanched ones. 2. By exposing the plants in the solar spectrum; and 3, by placing them behind solutions of chlorophyll. By these different ways he has arrived at the same results, viz., that the presence of chlorophyll markedly increases the action of the light on transpiration; that it is the rays which correspond to the absorption-band of the chlorophyll spectrum, and not the most luminous rays, which excite transpiration; and lastly, that the rays which have traversed a solution of chlorophyll have only a slight influence on transpiration. Other colouring matters, as xanthophyll, for instance, may act in the same way as chlorophyll, but to a less extent. M. WIESNER does not deny that the opening of the stomata may accelerate the transpiration. But the very marked transpiration of young Maize plants, the stomata of which were closed, and the slight transpiration of a *Hartwegia comosa*, the stomata of which were widely open in obscurity, suffice to show that this cannot be the principal cause of the transpiration in the light. In a very positive manner, but in a less degree than in the case of the luminous rays, the obscure calorific

rays act. As to the chemical rays beyond the violet their action is null or very slight. Whatever may be the nature of the rays, they always act in raising the temperature of the tissues. The physiological object of the absorption of light by the chlorophyll is no longer a secret.

— A local paper states that a marriage lately took place at Boston, when the assembled friends, in the absence of flowers, strewed the path of the bride with feathers! Were they goose feathers?

— That dread visitation, the "spot," is sometimes apt to affect plants of CARNATIONS AND PICOTEES at this season of the year, and it needs to be guarded against if the stock of plants is to be maintained healthy and vigorous. The "spot" is a sad disfigurement to the leaves, besides perilling the well-being of the plants. Two things mainly operate to produce it—overcrowding the plants, and excessive moisture of the roots. It is very necessary that the air freely circulate among the plants, and therefore undue crowding should be avoided, and the contact of the foliage prevented as far as possible. Not only should the pots be well drained, but the bottom of the frame should be so constructed as that all wet passes away quickly. It is always wise in making cold frames so to form the bottom that as perfect a drainage as possible be secured. Those who grow Carnations and Picotees for exhibition should have them well established in the pots in which they are to be wintered in the cold frame. Air cannot be too freely given all the while the weather is favourable. Water should be administered sparingly, and only when it is required, and growers invariably recommend that it be done in the morning. The best aspect for the frame during winter is a north or easterly one, as the plants are less liable to excitement than when it is full south, and the sunshine falls directly on it. Where a large collection of plants is grown, it is well to go over them occasionally, brushing away any greenly and dust deposits, for cleanliness is of great importance to the well-being of the plants, and the employment of the scissors is necessary to remove any decaying foliage. Advantage is taken of the leisure peculiar to the autumn season to prepare and mix together the compost for potting the plants into the flowering-pots in spring. It is best to do this in the open air on a dry day, and then place it in a shed or some such sheltered place to keep it from rain. "Nothing is better," writes a well-known cultivator, "than good sound loam, the top spit taken from an old upland pasture, stacked for twelve months in a sharply ridged heap previous to using. Of this take three parts, and let the fourth part be composed of well-decayed cow or stable manure and leafmould. As the heap is turned from time to time, a little quicklime may be used to destroy very small worms."

Home Correspondence.

Madame Cornellissen Fuchsia.—I am glad to see my old favourite Fuchsia so well spoken of as a hardy variety outdoors, but besides being such a beautiful-habited free-flowering kind in the summer its great value with me is as a winter bloomer, and those who have to keep up a display at that season will find it a great acquisition. Old plants are the best for the purpose, as they can be made to do double duty by being got in early in the season and then rested a bit by being kept partly dry, when if pruned back a little and started again they will be at their best about Christmas. The most suitable place to grow them is in any situation where they can get perfect shelter and shade during the hottest part of the day, as there they make shorter-jointed firmer wood than they do under glass, and are therefore more floriferous. If such as the above or others could be crossed with any of the evergreen winter-blooming varieties like serratifolia, it is likely something good might be obtained, but although I have tried it I have not as yet succeeded in getting any seed up. I hope, however, with the hint given that others may do so. *F. S.*

Neja gracilis.—This is certainly one of the prettiest of all the great Composite family for our rockworks. It will succeed in the open, but the best plant I have happened to lay hands upon is planted in a sunny position on a small rockwork. At the present time it would not be very difficult to count nearly one hundred flowers in different stages of development. Its bright yellow capitula, with the dark

slender foliage, are pleasing. I cannot agree with Sir J. Paxton when he terms it a "worthless greenhouse plant." *F. T. Riches.*

Tanacetum fruticosum bracteatum.—Will you kindly allow me to correct an error which, by means I am unable to explain, appeared in your last issue, respecting *Tanacetum fruticosum bracteatum*, described by Mr. Clarke; he says, "seeds sent to England by Dr. King from Mr. Gammie from Sikkim, &c." Of course one would not doubt that Dr. King has sent seeds home, but the seeds from which the plants were raised, forwarded to Mr. Clark through Mr. Baker, were sent to Mr. Gower by a private friend of his at Sikkim, among a host of other good seeds—*Cyananthus incanus*, and a very distinct *Androsace*. The latter no doubt will shortly be introduced to the public. *F. T. Riches, 4, Avon Terrace, Deje Road, Lower Tooling, S.W.*

The Palace Shows and the Royal Horticultural Society.—While deeply sympathising with the Royal Horticultural Society in its financial difficulties, I would ask it not the duty of all gardeners to get an honest pound when they have the chance? If so, why are we to be blamed for competing for prizes, and comparing our productions with those of our neighbours in a friendly manner at the Palaces or Aquarium when an opportunity offers? It cannot injure horticulture, or the Royal Horticultural Society, any more than County Agricultural shows injure farming or the Royal Agricultural Society. The frequenters of these Palace shows are mostly those who cannot visit Kensington or Regent's Park. [The Royal Botanic Society's shows, being closed to the general public, should not be introduced into this discussion, Eds.] I wish the Royal Horticultural Society would hold a September show with moderate gate fees, and offer reasonable money prizes to enable exhibitors to cover part of their expenses. They would meet with such success as would show that the Society was not forsaken. I do not say that this would prevent the holding of the Palace shows, as the Palaces must necessarily hold a variety of attractions to carry on successfully. It may not be out of place here to protest against what is perhaps the most disheartening grievance connected with these shows, that is, the withholding of prizes, as is too often done, in the most indiscriminate manner, by some judges, even when prizes are offered unconditionally. *F. H. Goodacre, Elvaston, Nov. 6.* [The withholding of prizes may be, and no doubt is, disheartening to exhibitors, but having a very wide experience of shows, we have come to the conclusion that prizes might be withheld much oftener than they are, with great advantage to horticulture. It lowers the standard of cultivation to award prizes to inferior productions, as is too generally done now-a-days. Eds.]

The Royal Horticultural Society: The Wilson Raft.—Possibly owing to my having put wrong stops a sentence in my letter, p. 595, does not convey the sense intended. I meant to say that in the great days of Chiswick shows the Society, though fashionable and magnificent, was poor, and persecuted by weather, as it has so often been since. I might have added in the letter on the "Wilson raft" which you were good enough to print, p. 599, that in the course of experiment we made a couple of boxes of large slabs of cork. Into one of these, half filled with soil, was placed some Cress from the orchard-house border, where it thrives, but has not the fresh pungency of that grown naturally. The Cress soon overtopped its cradle, and is now a huge floating bush, which gives us a good regular supply of excellent Watercress. I think this hint may be usefully taken by many who have a tank or small pond of clean water. I have lately come on some rather curious facts connected with Lilies. If you care to have them I will send a letter in time for next week's *Gardeners' Chronicle*. *George R. Wilson.* [Do please. Eds.]

Cypripediums.—These are a most useful class of plants for the Orchard-house, having the singularly beautiful formation which is so distinctly marked in Orchids. The very name of Ladies' Slipper is pleasantly suggestive, although the shapes of some of them are not very complimentary to the ladies' feet. The *C. caudatum* with its marvellous appendages, the ribbons with which to tie on the slipper, seems to have been made to order, and finished by some expert workman, rather than to have come to us naturally; the *C. barbatum nigrum* might just have been polished with Day & Martin, while the charming and exquisite *C. niveum* makes one think of the wedding or the ball-room, and the very prettily painted *C. Schlimii* is suggestive of the slipper of comfort, the foot-cover made by the hand of affection and taste for the cosy parlour fireside. I admire these beautiful things because they are beautiful and because their beauty is so enduring. There is here now in bloom the lovely *C. Dominianum*, which plant has been in flower nine months. *C. niveum* was quite six months in bloom. *C. villosum* and

C. barbatum had their blooms cut off long before they faded to make room for others, while now in November there are spikes enough in bloom and coming into bloom on *C. Roetzii* to last the entire winter, while *C. concolor* and *C. Schlimii* are in charming flower, and *C. Argus* and others are coming on full of promise, so that we may rely upon this section as perpetual bloomers all the year round. *W. Payne, Belmont, the seat of John Marshall, Esq., Taunton.*

The Poultry Yard (Cramp in Fowls).—A few days since I found a fine young pullet evidently suffering from cramp in the legs, as it crouched about, and was unable to walk except in the most painful way. I caught it, and immersed its legs into a bowl of warm water for a few minutes, then put it into a basket partly filled with litter, and covering it over kept it close confined for the night. Next morning when let out and fed alone, it was still stiff, and evidently better, but I did not intend that it should escape from the outhouse in which it was placed at once. Fortune, however, unexpectedly favoured it, and in a short time it was running about with its mates evidently quite well, and so it has since remained. I have thought the mention of this simple cure for cramp, if such it really was, would be of interest to poultry keepers. *A. D.*

Cinerarias and the Frost.—A few weeks ago a writer in the *Gardeners' Chronicle* advised its readers not to be too much in fear of Mr. Frost as regards this plant. For a long time I have looked upon Mr. Frost as a great foe to it—let me tell you how. Nearly thirty years ago, I had a house of mixed plants under my care, most of them Cinerarias, some fine bushy plants, but Mr. Frost paid this house a most unexpected visit in November, and having effected an entrance, seemed to cry "Havoc!" and let slip the dogs of war, for by morning there was not a Cineraria standing upright, and many of the poor things were killed. Some eight or twelve years afterwards I was walking through a nursery where plants were made a speciality, and on coming to a range of framing I was struck by a sad sight, for before me stood a lot of finely-grown Cinerarias, completely spoiled for the season, for I think this was in November; the successful efforts of a whole summer destroyed in one night. In the face of two cases so sad, can there be any need of advice to any one not to let Master John have anything to do with his Cinerarias? *Thomas Reid, Flaxley, Gloucestershire, November 10.*

Galvanised Iron and Fruit Trees.—When I read the information given at p. 533 I was a little surprised. The quarters of our kitchen garden were all done round five years ago by Messrs. Brown & Co., of Cannon Street, with stout galvanised trelliswork, and, when finished, were all planted with espalier-trained fruit trees, Apples, Pears, Gooseberries, Currants, and Raspberries. Since they were planted it would be impossible for them to have done better. I have not noticed a canker on any of the trees. I may mention that when we are tying them we always twist the matting twice round the wire before tying it round the shoot. The old *Clematis flammula* runs along the wire very freely. *F. Beattie, Mount Moun, Mill Hill, N.W.*

Glass Copings to Peach Wall.—Mr. Miller must be singularly favoured as regards climate if the photograph of which you give an illustration in last week's *Gardeners' Chronicle* may be taken as representing a fair specimen of the Peach trees at Coombe Abbey. [It does. Eds.] The wall on which it is growing appears to be a very high one, for on counting the courses and allowing four to the foot, which is the usual run for ordinary-sized bricks, I find that the height shown is 11 feet, and as there is no coping seen at the top it may be the gable end of a building [The top with its spouting was not shown] instead of a garden wall, and if so the overhanging eaves or other shelter has perhaps been the means of saving the crop. [There are no eaves near.] Out of a great number of trees on a wall having an east-south-east aspect, and all treated exactly alike, we had one Elrage Nectarine that set and swelled out a very heavy crop, while all the others were nearly bare of fruit. These freaks are difficult to account for, and although fully agreeing with what Mr. Miller says with regard to the necessity of scrupulous cleanliness in keeping down insects, we must do something by way of protection if we are to go on attempting to grow Peaches on open walls. I have unfortunately had no opportunity as yet of testing the utility of glass copings, and have only seen them in use in one instance, and that during the present season at Sudbourne Hall, where I think without a single exception the trees had all full crops of fruit, and in point of health were all that could be desired. I was informed by Mr. Pottle, the able gardener there, that all the protection they had was in addition some old fishing-nets strained from the coping to the foot of the wall,

and if the trees I saw were in that condition owing to the protection afforded by the overlapping glass above them and the nets in front, there can be no question as to its value, and the sooner we have such aids to outdoor fruit culture the better, as in the end they are far cheaper than the sorry contrivances of blinds and such-like appliances now in use. In seasons like the present they are of no avail whatever, and what is wanted is something that can be depended on as being effectual, which these glass copings would appear to be. It is much to be regretted that those who have had some years' experience of them do not speak out, that others may profit by the failures or successes, as the case may be, for to go on year after year without being able to get any Apricots, Peaches, or Nectarines, the trees of which take up so much time and attention in their management, is most discouraging, and alike vexatious to employers and gardeners. Glass copings from 2 to 3 feet wide ought not to be expensive, and if the frames and supports are made of metal, as those in use now are, they ought to last almost as long as the walls to which they are attached. To all appearance they are just the thing needed, as they are a compromise between a house and the makeshift appliances for protection that have been so long resorted to. I intend giving them a trial, and should have put up a considerable length, but hesitate to do so till I hear more concerning them, and as it may be the same with many others, I hope those who have them will not keep silent any longer. Mr. Shingles, of Tortworth, I see, appears to have found them a failure, but why this should be I am at a loss to imagine unless there is a long stretch of wall without breaks, in which case the draught would be so sharp as to lower the temperature considerably. No doubt but that projections about every 50 feet or so would be a great help in stopping the cold current of air that dashes itself against the brickwork, and in addition would form a tie and strengthen the coping, besides giving it a more ornamental appearance. A coping with breaks of this kind, with a double fishing-net suspended in front, ought to be proof against 10° of frost, taking into account the heat the bricks absorb from the sun, and which, under such a covering, is only parted with slowly owing to its escape being cut off in the vertical direction. It is a well-known fact that even a newspaper laid over plants will often preserve them from being frozen under glass, but this is owing to the way it intercepts radiation and cuts off the line of communication between the upper and lower air. The same thing occurs if a few evergreen branches overspread the ground, and one would expect a broad coping to act in a similar manner, but whether they are to be relied on as efficient in all seasons is another matter. If they have done as well in other places as the one that came under my notice they must be valuable aids in any garden during such trying springs as the past, when the cold was so continuous as not only to destroy the bloom, but to cripple the young tender leaves so much as seriously to affect the health of the trees. The only objection I can see to glass copings is that they keep off the rains and night dews from the foliage, but with a garden engine and the use of plenty of water the trees are just as well situated for being kept free from spider and other insects as those grown in houses in the ordinary way. J. S.

Parachetus communis.—This is an exceedingly pretty creeping perennial, either suitable for a damp place on the rockwork or for the open bed or border. Its Clover-like foliage, apart from the large blue Pea-like flowers, is very pleasing. It is now copiously clothed with flowers fully exposed. It is a native of the mountains of Asia and Western Africa, and is the only species. J. T. Richey.

Shade-loving Plants.—For the information of "Trowel" I have enumerated some of the many shade-loving plants that are to be found in many places:—*Galanthus plicatus*, *Ægopodium podagraria* [Beware of this. Eds.], *Helleborus niger*, *atrorubens*, *foetidus*, *viridis*; *Galeobdolon luteum*, *Corydalis bulbosa*, *Acanthus mollis*, *spinosissimus*; *Gentiana acaulis*, *Caltha palustris plena*, *Aconitum Napellus vesiculosum*; *Geranium Endressii*, *Veratrum nigrum*, *Hemerocallis flava*, *fulva*; *Actæa spicata*, *Colchicum autumnale plenum*, *Asarum europæum*, *Hesperis matronalis*, *Lunaria biennis*, *Meconopsis cambrica*, *Allium Moly*, *paradoxum*; *Doronicum pardalianches plantagineum*, *Leucojum vernum*, *Narcissus poeticus*, *Alströméria aurea*, *Crocus sativus*, *Omphalodes verna*, *Anchusa semper-virens*, *Rhodiola rosea*, *Polygonum Bistorta*, *Cnicus heterophyllus*, *Cyclamen hederæfolium*, *europæum*; *Vinca major*, *Gagea lutea*, *Fritillaria imperialis*, *meleagris*; *Sedum album*, *Anemone apennina*, *Nemosa plena*, *Funkia ovata*, *coerulea*; *Asperula odorata*, *Ficaria ranunculoides plena*, *Lysimachia ciliata*, *Symphytum bullatum*, *Aster Tradescanti* and *dumosus*, *Pulmonaria officinalis*, *Erinus alpinus*, *Scilla bifolia*, *sibirica*; *Astrantia major*, *Lilium Martagon*, *Dondia Epipactis*, *Ornithogalum umbellatum*, *fimbriatum*, *narbonense*; *Atropa belladonna*, *Saxifraga umbrosa*, *Andrewsii*; *Ferula gigantea*, *Sedum Telephium*, *Ery-*

thronium dens-cannis, *Tradescantia virginica*, *Hepatica triloba*, *Euphorbia Cyparissias*, and others that might be enumerated, that afford pleasure in our shady walks, glens, and wildernesses. *Constant Reader*.

Fowl's Food.—Probably no kind of food is more commonly given to fowls than is Barley, but poultry fanciers have their favourite diets and mixtures, most of which is probably quite as dear and less nutritious than firm clean corn. Fowls that have a good run find an abundance of soft food, and if no hard corn be given them the gizzard, Nature's crusher, has little to do, and this lack of work may probably lead to many derangements. I feed my fowls regularly twice a day, that is, the first thing when let out in the morning, and again at mid-day, with a good measure of Maize and Barley in equal quantities; and I observe that, either because the former is the larger, or because it is sweeter, and therefore better appreciated, the poultry pick up every Maize corn before touching the Barley. In addition to this and what in a good run they can pick up, they get now and then a few boiled Potatoes and household crumbs, but in no case is the soft food so eagerly eaten as is the corn. On this diet they thrive well, and are at any moment fit to be prepared for the table. A. D.

Arundo Donax (p. 597).—Are Mr. Hanbury's plants of the *Arundo Donax* which flower so freely in the open ground? If so, his plants are an exception to all that I have seen. I have grown it for many years and the plants flourish well, but they have never flowered. The only other instance of which I can find a record is in the *Hortus Collinsonianus*, in which there is the following notice:—"Mem. Arundo Donax in flower September 15, 1762; the first time I ever saw it, but this very long, hot, dry summer has made many exotics flower. Mr. Miller is greatly mistaken to say that it dies down every year; in my garden the stalks have continued some years to make annually young green shoots from every joint; it bears a handsome tassel of flowers.—P. Collinson." *Henry N. Ellacombe, Bilton Vicarage*.

Do Roots Digest?—The roots of plants have the power of digesting mineral and other inorganic substances in the soil with which their rootlets may come in contact, in the same way that the vessels of animals have the power of digesting organic substances which may come in contact with their exuding vessels, either in the mouth, stomach, or intestines. What I mean by roots and vessels having this power is, that they excrete liquids holding matters in solution which are able to dissolve inorganic and organic substances. And here analogy, asserted to be "a fertile source of error," steps in and assists us, and a wonderful aid it is in enabling us to establish new and accurate conclusions in matters before unknown. We will, before passing to the offices of the roots of plants, consider the following well-known operations in animals, and compare them with others not so well known. We will take the secretions of saliva and gastric juice, the one alkaline the other acidulous, each having the property of breaking down and rendering soluble, *i.e.*, capable of being absorbed, matters which might be in the mouth and stomach until corruption set in, unless they were acted upon by these digesting juices. It is well known that during the digestion of a meal a very large quantity of the fluids, charged with an alkali and an acid, flows into the mouth and stomach, but, as rapidly as it flows in, with equal rapidity it flows back again from whence it came, but by another set of vessels, so that there is never present any large quantity at a time. These fluids hold in solution the food—now rendered soluble and capable of being absorbed by the surfaces—with which they come in contact. The same identical fluid, charged with fresh alkali and acid, returns again and again to break down and rob the mouth and stomach of its contents, and store them up in vacant spaces of the animal. We may compare this fluid to a vehicle or carrier taking goods to their destination and returning empty for more, or like a squirrel loading itself with nuts, depositing them in its storehouse, and returning empty-mouthed for more. The above process seemingly takes place during the digestion of carnivorous plants. I have described all this to prepare your readers for the comprehension of the action of the roots, or rather rootlets of plants, which action I believe to be precisely analogous to that of the excreting vessels of animals, rendering soluble and preparing food suitable for their different organisations; as I said before, the plant has to prepare inorganic matters, organise them, and render them suitable for the digestion and organisations of animals. I had, several years since, arrived at this conclusion regarding this digestion of mineral food in the soil, for it must have been at least twenty-five years since that I had a slight controversy with the late Dr. Lindley in the *Gardeners' Chronicle* on the exudation of a fluid from the rootlets of plants holding carbonic acid in solution.

I affirmed that it was impossible for the delicate fibrils of the roots to push through a hard and dry soil, away from the influence of rain and air, unless some chemical means were called into action. Professor Lindley denied my theory, and brought forward several interesting examples to prove that roots were capable of thrusting themselves through hard substances, merely by the mechanical force of growth, and that nothing of an acid nature had ever been discovered to exude from roots. I have had several articles on this subject at different times both in the *Chronicle* and *Journal*, and believe that, at last, I satisfactorily proved my theory; at all events, in a recent letter from Mr. Darwin, I find that a German Professor proved experimentally, by growing plants in marble pots, that roots did exude carbonic acid, and corrode marble. I do not quite see how he arrived at any accurate conclusion unless he banished everything of a carbonaceous nature from the pot, for, as I afterwards discovered, free oxygen also exudes in solution from roots, which would combine with any carbon in the soil, and, forming carbonic acid, would act on mineral substances. He may or may not have been aware of this, and taken precautions against it, but great care and delicacy is necessary in making all these experiments. As an instance of the roots of plants passing through a hard dry soil I will relate what I saw at Woburn last year. The gardener pointed out a well which had been dug close to a viney. He showed me where the roots of these Vines had penetrated a hard dry bed of clay, immediately beneath which was a bed of sand in which the roots were then revelling. *Observer*.

Verbena venosa.—I am glad to see attention drawn to this useful old favourite. It has qualities to recommend it to be more extensively used. It is a good early and continuous bloomer on the borders. It is also an excellent bedding plant, and very telling when mixed with a white variegated Pelargonium. It is quite hardy, and easily managed. When the frost spoils the flowers in the beginning of winter we lift it, and plant it in any corner where the soil is light. It begins pushing through the soil, like the Mint, by the middle of April, and by bedding-out time is just coming nicely into bloom, when it is again transferred to the flower beds, and stands either in hot sun or heavy rain better than almost any other plant; and, as you say, the rabbits very seldom touch it. *James Beattie, Mill Hill*.

The Best Cucumber.—I have been greatly interested in reading the correspondence in your columns on the best Cucumber, especially so as it regards the Telegraph, which was raised here in my father's time about thirty years ago, and named and sent out soon afterwards by Messrs. Fisher, Holmes & Co., of Handsworth Nurseries, under the name of Telegraph, which was the first Cucumber of that name ever sent out. I am aware that many varieties of Telegraph are advertised, upon which I will make no comment. I have grown it myself for the last twenty-five years, without ever having disease or failure; and during that time, I am glad to be able to say, instead of deteriorating it has improved, still holding its own for all purposes against all others, and is at the present time in greater demand than ever. One correspondent speaks of Telegraph and Blue Gown being grown together, and treated alike, "but Blue Gown held on and was producing beautiful fruit, 20 inches long, at least a month after Telegraph had given out." On Friday, November 2, I cut very nice Telegraph Cucumbers from plants which have been bearing all through the season in frames where the temperature for the last month has often fallen to 55° on account of the cold wet weather which we have experienced. I hope I shall not be thought egotistical in writing this letter, which I have done to show the length of time Telegraph has maintained its position amongst Cucumbers, which I consider a strong recommendation. J. Bailey, *Wentworth Castle Gardens, Barnsley*.

Cryptotype.—As you have referred to my new photographic process for rapidly obtaining pictures upon boxwood blocks for engraving, perhaps a few words of explanation from me may interest many of the readers of your paper who may have noticed the naturalness of many of the views and garden and greenhouse scenes which for some time past have weekly appeared in the *Gardeners' Chronicle*. To persons unacquainted with photography and engraving it no doubt seems as easy to produce a photographic image upon wood as it is to print a photograph upon albumenised paper, but there are three very great difficulties in the way of printing a photograph upon wood. 1. If an attempt is made to prepare the wood in the same way as sensitive paper is prepared, some change takes place in the wood which turns it to a mahogany colour. 2. The usual photographic preparation also injures the wood. 3. Photographs upon paper have to be subjected to repeated washings; now if boxwood is washed or placed in water it is greatly damaged for engraving purposes. For some years past photographs have been placed

upon wood for engraving by dexterously peeling films of glass and transferring them backwards on to boxwood blocks. But a film of collodion on a boxwood block is highly objectionable in several ways. 1. In fine work the engraver does not know whether he has cut through the collodion and reached the wood; and if the wood is not reached, then, when the block is cleaned, the engraver has to recut his work, for the fine engraving will have vanished with the film. 2. Sometimes the collodion will peel off like a pancake. 3. At other times it will be brittle, and so pieces of the picture will fly away from the wood at the touch of the graver. A process is known for removing the collodion, but this leaves the print so pale, unsatisfactory, and evanescent, that it rubs off on being touched with the fingers. Hitherto all attempts have ended in brown or grey pictures, and these colours are objectionable in wood engraving. The process perfected by me entirely gets over all these difficulties, for the block is never placed in water or washed, there is no preparation of the wood, and there is no collodion. All that is present upon the naked wood is a permanent jet-black image of the object copied. The discovery (which for obvious reasons is kept secret) was not accidental. It was only arrived at after nearly three years' incessant daily work in one direction. Nearly every day of all this long period saw a more or less disheartening and often expensive failure. That it is a success there is no room for doubt, as during the last six months it has been largely tested in different directions by many engravers, and always with uniform and perfectly satisfactory results. For half a year nearly all the more elaborate landscape and garden subjects engraved by my father for the *Gardeners' Chronicle* have been first placed upon the wood by me by this process. The very natural appearance of many of the subjects is owing to this fact. Many portraits have of late been engraved direct from the cryptotype image, and Mr. Berkeley's portrait mentioned by you is now nearly ready for printing. The process is also adapted for producing an enlarged image on the wood of any object direct from the field of the microscope, and I am now executing a number of subjects of this nature. *Arthur E. Smith, 15, Mildmay Grove, London, N.*

The Entire-leaved Tulip-tree.—With regard to the "*Liriodendron tulipifera integrifolia*," spoken of by Mr. Meehan, I send you with this leaf that you may determine whether or no it is identical with that sent by him [Yes]. I do not think that it is as rare as your correspondent supposes, although I am aware that it is by no means a common tree. I think I may say that all the trees we have here are seedlings. The shape of the leaf is very peculiar, for as that of the normal type is likened to a saddle, the outline of this gives very nearly the cross section of a lioe-of-battle ship, the leaf-stalk forming the keel and the apex the deck, minus bulwarks. *T. Smith.* [Other correspondents write to the same effect, and we are ourselves conversant with more than one example. *Eds.*]

Dean's Snowball Cauliflower.—Last year I had sent me some seeds of this variety for trial, but owing to the dry weather it came up badly, and ultimately was eaten off by the fly. But I resolved to give it another trial, and this year procured a packet of seeds, which I sowed in pans, pricking off and transplanting the seedlings when large enough, and by keeping them well watered during the dry weather succeeded in having a good supply of the most beautiful Cauliflowers that any one could wish to possess; and a basket of them did me "good service" in a collection of vegetables at a local exhibition, with which I gained a 1st prize. This Cauliflower is the very thing for exhibition, as it possesses the merit of not being too large, is compact, and as white as the snow from which I suppose it is named. All exhibitors of vegetables should grow it. *J. Batters, Gr., Chilworth Manor, Romsey.*

Cattleya gigas, a Winter-flowering Plant.—We have a plant of the above with twelve fully expanded flowers. It is deliciously scented. Some ladies who have seen it say the smell is a mixture of Violets and Primroses. *R. Carr, The Gardens, Taverham Hall.*

The Deciduous Cypress.—I have observed with much interest the remarks of "P. P. C.," and also of H. W. Ward, in your numbers of the 27th ult. and 3d inst. respectively regarding the deciduous Cypress. Will you allow me to supplement their statement by saying that there is here an avenue nearly half a mile in length of these magnificent and beautiful trees, numbering upwards of fifty. On one side of the avenue the trees grow close to, and spread their roots half-way across the River Lea—the other side of the avenue is some 7 yards from the river. I have no means of knowing the age of these trees, but from circumstances that have come to my knowledge I have no doubt they are upwards of 100 years

old. Their height varies from 20 to 75, or perhaps 80 feet, and some of the larger ones measure 9 feet 6 inches to 9 feet 8 inches in circumference, at a distance of 4 feet from the ground. The trees adjoining the river-side throw up from their roots large excrescences which have a peculiar but almost indescribable appearance. These trees are now in their richest autumnal garb, and their graceful foliage sweeping to the ground is an object of much attention to those who delight in arboriculture. *William Gurney, Brocket Hall Gardens, Herts.*

Lilium Kramerii.—The most refined of all Lilies and the most beautiful is *L. Kramerii*. The exquisite delicacy of the colour and the pleasing fragrance emitted enhance its value as a conservatory plant. Mr. Boscawen has to-day sent me a flower, and I had no idea that this species would flower in November. I shall be glad to know the experience of other Lily cultivators whether this is an exception or a characteristic. All my specimens have ceased flowering for well-nigh two months. Anatum I had in bloom from July, and had I housed them I believe the succession would have continued up to Christmas—the only Lily I am acquainted with which seems to have no specific season for blooming. Another remarkable thing in *L. anatum* is the variation in the size of the flower, as well as the diversity in the markings. During the past season I have had flowers not more than 3 inches in diameter, and others a foot; and I have even seen flowers of this Lily 15 inches in diameter. *P. E.*

The Tomato Crop.—Our Tomatos planted on a south border on June 2 grew luxuriantly, set a good crop of fruit, which attained to the usual size, but 90 per cent. refused to ripen in the open air, and some of my neighbours' Tomatos were just as bad. On the same border were placed six medium-sized pots with two plants in each. The pots were well drained, and equal parts of fibry loam and old Mushroom-beds used in potting the plants, which made satisfactory growth. After their fruit were set, manure-water was liberally used until the fruit showed signs of colouring. From that period the plants were merely kept from flagging. Without exception, every fruit ripened in the open air. The plants grown in the pots were trained on the wall in the same manner as those planted in the border. *Thomas Lloyd, Gr. to John M. Fraser, Esq., Mowell Park, Wallingford, November 12.*

Laying Down of Broccoli.—Why, I ask, do gardeners generally lay down Broccoli with their heads towards the north for protection rather than the south? My experience is that Broccoli laid toward the south resist the influence of frost much better, but I will not enter into the why and the wherefore here, only simply say to those who have never adopted the plan I advocate—try it. *J. Gardner, Elsham Hall Gardens, Briggs.*

Carpet Bedding: Herbaceous Plants.—The best answer to Mr. Thomson's letter, p. 599, is your report of the meeting of the Royal Horticultural Society's Floral Committee, p. 600, where you describe the "very choice collection of cut flowers of various hardy herbaceous plants," exhibited by Mr. Parker, of Tooting. I should be very sorry if our herbaceous borders had to be "torn up at the first frost." *George F. Wilson.*

Irish and English Ivy.—I have often wondered exactly where Irish Ivy begins and English ends, and after reading your correspondent's letter I am as far off a solution as ever. There are in this neighbourhood many acres of woods carpeted with what I suppose we may call Irish Ivy, and it has the long leaf-stalk so objectionable to Mr. Williams (all plants in shady woods, I believe, have longer leaf-stalks than similar plants in the open); and in this same neighbourhood there are miles of stone walls covered with so close a verdure of Irish Ivy (again) as to look almost like paint—the difference, I suppose, between sunshine and shade. It would I think be quite possible in a day's ramble to find as many varieties of Ivy as there are days in the year, but none except in hedges or woods with long leaf-stalks. I have seen ruined towers in both countries mantled over with what to my unpractised eye seemed to be one and the same thing—English or Irish Ivy, and after the ruin has become covered the Ivy loses its palmate character and assumes a more entire leaf. This it always does when it has reached the top of a wall, a tree, or any object up which it has climbed. I suppose there are large and small-leaved forms in both countries; the large-leaved one is, I believe, in England called Irish Ivy, and here the reverse is the case. As to Irish Ivy on a wall requiring an amount of clipping, signboard, &c., if it is clipped at the proper time, just as growth is beginning, you don't have long to wait for the fresh mantle; and to my mind to watch the new beautiful pea-green growth developing so rapidly lends an

additional charm. I have never yet seen Ivy, of any country or form, where there was room for twenty leaves in place of one that it had. Another word about the difficulty (?) of propagation: there is one seed-bed not far from where I write that contains not less than 100,000 plants. *T. Smith, Newry.*

Horticultural Exhibitions: General Principles.—With your permission I should like to say a few words on the "general principles" growing out of the closed discussion. Your excellent leader seems to me to have an important bearing on the subject, and with which I quite agree. I say again what I said before, that one main object the joint-stock companies have in view is to bring people together to consume the refreshments they have on sale, or, to use your more elegant phraseology, they "make horticulture a means to an end." Then there is (what seems to me) another evil—I allude to the large number of shows held in a small area. I am not alluding to cottagers' shows, but shows at which gentlemen's gardeners and nurserymen exhibit, the latter very often against their will, inasmuch as their time would be more profitably spent in looking after their business. A friend of mine in the seed trade was speaking with me the other day on this subject, and informed me that it was becoming a very serious matter—the incessant calls for this and that little society. The picture he drew was something in this way:—I go on my rounds in a village, and am asked to subscribe to the horticultural society; drive two or three miles further on to the next village, the same application is made. The applicant, perhaps, is told, Why I have just subscribed to the society in the village I have just left. Yes, the answer is, but "Codlin is the man, not Short;" and, as you say, "all such shows accomplish little or nothing creditable to horticulture." Then, judging from the report published by the National Rose Society, it was a financial failure, and I am sure it must be very humiliating to the excellent men composing the committee of that Society to issue a schedule and at the close of their labours to be obliged to ask the exhibitors to take 50 per cent. from the amount awarded to them. What are the inferences to be drawn from these things? Clearly, to my mind, one is that the efforts of horticulturists are too diffuse—there is sadly too much sail spread; and until differences are sunk and our efforts are more concentrated I fear that this state of things will continue; and inasmuch as I have frequently come in contact with many gentlemen who have expressed a desire to have a strong national horticultural society, I have been very much surprised to observe the same gentlemen act in a way that seems to me to thwart the laudable object they have in view. *A. B.*

Mandragora microcarpa (p. 595).—There seems to have been always some confusion about *M. microcarpa* and *M. autumnalis*; but I have little doubt they are synonyms of the same plant. Sweet published *M. autumnalis* (*British Flower Garden*, ii. 325), but afterwards withdrew the name in favour of Bertolini's *M. microcarpa*. The plant seems to be perfectly hardy, and I consider it one of the very best of our winter and spring flowering plants. Here it began to flower last November, and continued in flower till May. During that time it threw up several flower-stems, and at a little distance the flowers looked like a bunch of *Anemone pulsatilla*. For a long time I could see no sign of fruit, but in April I at last found a few fruit hidden away under the leaves close to the ground; and I was induced to believe that these fruit were the produce of some inconspicuous flowers, which fruited like the inconspicuous flowers of the Violet; but this is a mere guess. The plant is now again throwing up its leaves, and I hope will flower. *Henry N. Ellacombe, Bilton Vicarage.*

Reports of Societies.

Scottish Arboricultural: November 6.—The twenty-fourth annual general meeting of this Society was held in the class-room of the Royal Botanic Garden, Edinburgh, the Right Hon. W. P. Adam, of Blairadam, M.P., President, in the chair.

The President opened the proceedings with an address, in which he referred to the gradual, steady, and sure progress which the Society was making, not only in the number of its members, but in the influence and authority with which it spoke to all connected with arboriculture. He urged all landed proprietors interested in rearing woodlands, and all foresters engaged in that most interesting pursuit, to become members of the Society, and to assist in the only way at present open to them in the good work of promoting and extending the knowledge and practice of arboriculture in the kingdom. Whereas the number of members in 1858 was only 168, and the income £39 10s., this year the membership was 776, and the income £351; and this advance they owed very much

to the valuable services rendered to the Society by his distinguished predecessors in the chair—Professor Balfour, Dr. Cleghorn, and Mr. Hutchison, of Carlourie. In 1871 the Queen was graciously pleased to become patron of the Society. Her Majesty had always evinced great interest in the rearing of woodlands, and on her own estate in the Highlands much has been done in this way. He observed also that about the same time they had become affiliated to the Royal Society (Botanical?), which he considered a great step in advance, and most useful and valuable for the Society. It should be an inducement to all who were interested in their success to use greater endeavours to bring their powers of accurate observation to bear on the natural phenomena of which so many came under the eyes of practical foresters, and so render that assistance to the march of scientific progress and knowledge which it became them to do as members of that important body. These two additions to the dignity and importance of the Society ought to be followed by another, and, in his opinion, they ought to use their earliest and best endeavours to obtain a Royal charter. He was not aware whether any and what steps had been taken towards the accomplishment of this object, but he could only say that if he could do anything towards furthering its attainment they might command his services. He had naturally asked himself what his claims were to the distinguished honour of being elected President. Those claims were not great, but he could at least say in the first place that he was a practical woodman, accustomed from his earliest youth to the use of the axe, and delighting both in the exercise and in the interest that it gave him. And he might add that he had brought up all his sons to the same employment, and that they had all acquired in their early years a thorough acquaintance with the use of that implement. In this they would all recognise him as a faithful follower of his late distinguished chief and leader, Mr. Gladstone. One often heard Mr. Gladstone derided for his partiality for woodman's work, but he was sure in that Society, whatever their political opinions might be, and whatever they might think of Mr. Gladstone as a statesman and an orator, they could all appreciate this trait in his character. He (Mr. Adam) was a humble but most persistent follower of Mr. Gladstone in this as in other things, and his general admiration for his character was, as they might suppose, much increased by knowing his proficiency in his favourite exercise. His other claim to the position in which the Society had placed him was, that he came of a race of planters and foresters. He was now the fifth in succession who had specially devoted himself to improving the estate of Blairadam more by planting than by anything else. He had this advantage over many other races of landed proprietors who had devoted themselves equally zealously to this occupation, and that the planting of Blairadam had become classical through a touch of the magic wand of that enchanter Sir Walter Scott. Blairadam, in its original unimproved state before the planting was begun, was a wild unsheltered moor, lying from 500 to 700 feet above the sea, with a certain amount of natural beauty, and with fine views of the plain of Kinross, Lochleven, and the Lomond Hills. But it must have been cold and bare; it was covered with Heather and coarse grass, and had only one enclosure, and one tree—an Ash—which, though it still grew vigorously, was far outtopped by the younger generation. He knew of no instance in the improvement of waste land that more thoroughly illustrated the value and advantage of judicious, continuous, and persistent planting than the estate of Blairadam. Silver Fir had always flourished luxuriantly, and was the most remarkable species of tree on the estate. There were four still living, of which he had the dimensions in 1811, in 1851, in 1862, and in 1877. No. 1 was 8 feet 4 inches in 1811, 13 feet in 1851, 13 feet 6 inches in 1862, and 13 feet 9½ inches in 1877. No. 2 was 8 feet 1 inch in 1811, 12 feet 1 inch in 1851, 13 feet in 1862, and 13 feet 3½ inches in 1877. No. 3 was 10 feet 5 inches in 1811, 12 feet 11 inches in 1851, 13 feet in 1862, and the same in 1877. No. 4 was 9 feet 2 inches in 1811, 11 feet 5 inches in 1851, 12 feet in 1862, and the same in 1877. These trees were planted about 1754, and others probably planted about the same time measured 15 feet 3 inches in girth, 15 feet 1 inch, 14 feet 8 inches. Five measured between 13 and 14 feet, six or more between 12 and 13 feet, and a great many others between 11 and 12 feet. Three very remarkable Hemlock Spruces were planted about 1757. He did not give the exact girth, as two of them divided into separate limbs near the ground, but one had a girth before dividing of about 12 feet, and the other two of about 10 feet. He was afraid that these trees had almost ceased to grow, and that their gradual decay might now be looked for. He had dressed some of them with compost, but without producing any perceptible advantage. The right hon. gentleman went on to refer to the necessity for something being done to establish a school of forestry in this country. He did not say that it would be an easy thing to obtain recognition from Government as to

this necessity. He had been long enough connected with the Treasury to know that in this country where any demand on the public purse had to pass the ordeal of Parliamentary criticism, and where the prevailing idea of the Government was to keep down the estimates, it was not till many years of pressing application, and till public opinion was brought to bear, that the public purse strings were drawn. This was one great difficulty in the way, and the other was that whatever might be the case in India and the colonies, they had at home no great forests under the charge of the Government, as was the case in most Continental countries, and this made it difficult to arrange for the practical education of foresters. Still, in spite of these difficulties and drawbacks, he could not but think that in a country like this, with so many dependencies and colonies where a knowledge of the science of forestry was necessary, not only for the protection of forests from destruction, but for the maintenance of that balance between woodland and open ground which was so necessary to preserve proper climatic conditions, it was absolutely essential that a school of forestry should be established. It was the duty of the Society to awake intelligent interest in this question, and he for one should be glad to do all that he could in and out of Parliament to further so praiseworthy an object. The necessity for good schools of forestry was illustrated by what was taking place in India. The wanton destruction of forests in that country had been going on for years. He could confirm from his practical observation as a sportsman all that had been said as to this in Western India. And who could say that the terrible famine which was now devastating some of the fairest provinces of that country, might not be directly traceable to the improvidence of man denuding the country of its natural vegetation, and so altering all the climatic arrangements of Nature.

On the motion of Professor Balfour, seconded by Dr. Cleghorn, a hearty vote of thanks was accorded to the President for his interesting address.

Mr. George Crichton, treasurer, reported that on the transactions of the year the balance had been slightly adverse, but that there still remained to the credit of the Society a sum of £319 10s. On the motion of Mr. R. Hutchison, of Carlourie, it was agreed to invest £300 in the name of the usual trustees.

Mr. Alexander Buchan, convener of the Meteorological Committee and secretary of the Scottish Meteorological Society, submitted the report on the meteorological experiments at Carnwath. In the outset he referred to a lengthened series of observations of great value which had been carried out in the German forests. The results of these observations worked out were that the mean temperatures of the stations outside forests and of the tops of trees in the interior of the woods were identical. Both sets of instruments were in this case placed in the full light and heat of the sun. The mean temperature on the surface of the earth in the wood was considerably lower than that at the top of the trees, and the mean temperature under the trees was also considerably lower than that outside the wood. Underground temperatures were also very interesting. For instance, the temperature of the soil shaded from the sun by the trees in the heart of the wood varied from two to four degrees below the mean of the outside of the wood under a full exposure of the sun, and protected by the grass. At the Society's station at Carnwath it was impossible to carry out the experiments so fully, owing to the want of observers and of the elaborate sets of instruments. The committee determined to confine their attention to the elucidation of the question of what effect trees had in modifying the temperature of the air around them and of the soil on which they grow. At Carnwath the Society had two sets of apparatus—one fully exposed to the sun's light and heat, and the other quite near, but completely sheltered from the sun. Taking the maximum and minimum thermometers in the open space, they gave a mean temperature from March to July of 46°.6, exactly coinciding with the mean of the dry-bulb thermometers. The mean temperature of the thermometers in the boxes inside the wood and protected by the trees was 46°.5, thus showing that when the sun's heat was increasing there was inside the wood a diminution of temperature compared with the outside of half a degree. The difference of the temperature of the soil in the two positions was even more marked. Inside the temperature of the soil 3 inches underground was 3°.2 below that of the open, at a depth of 12 inches it was 3°.5 below the open, and at a depth of 22 inches it was 3°.9 below the open; whereas outside the wood the difference was at 3 inches 1°.9, and at 12 inches 2°.1.

The President moved a vote of thanks to Mr. Buchan for his able and interesting report, and that the contribution by the Society towards the Carnwath experiments be continued.

Mr. M'Corquodale, Scone, said that he had carried out experiments himself, and found that where the trees were very crowded the ground was kept cool, and retarded the growth of the trees, for the bark

thickened, and prevented the flow of the sap. Therefore they ought to thin plantations more.

The President's motion was agreed to, and thereafter he vacated the chair to fulfil other engagements, Professor Balfour, senior Vice-President, taking his place.

Mr. M'Grigor, Ladywell, convener of the judges, gave in the report on the essays submitted for the usual prizes.

A silver medal was granted to Mr. C. F. Amery, forest department, North-West Province of India, for report on Indian Forests.

Silver medal to Mr. J. Hutton, Mackintosh Estates, Kingussie, for report on Woods and Soils on which they grow.

Bronze medal for report on Use of Dynamite and Tonite in Forestry, by Mr. D. F. M'Kenzie, Murthly Castle.

Silver medal for paper on The Movement of Fluids in Stems, considered in Relation to the Felling and Seasoning of Timber, by Professor W. R. M'Nab, College of Science, Dublin.

Gold medal for Collection of British Woods, by Mr. James Duff, Bayham Abbey, Tunbridge Wells.

Silver medal for Rustic Work, by Mr. James Scrimgeour, Hopetoun House.

The following officebearers for the year were elected:—

President—The Right Hon. W. P. Adam, of Blairadam, M.P.

Vice-Presidents—William M'Corquodale, Hugh Cleghorn, Professor John Hutton Balfour, Thomas Methven, and Robert Hutchison.

Council—John Anderson, P. S. Robertson, Robert Baxter, William Stewart, John M'Laren, William Gilchrist, Malcolm Dunn, William Gorrie, James Robertson, Alexander Richardson, John M'Gregor, C. Y. Michie, John Grant Thomson, Charles S. France, D. Scott.

Secretary—John Sadler, Royal Botanic Gardens, Edinburgh.

Treasurer—George Crichton, of Messrs. G. and M. Crichton, 18, Princes Street, Edinburgh.

Auditor—John Ord Mackenzie of Dolphinton, W.S.

Rev. J. Crombie Brown, LL.D., read a paper on Schools of Forestry, in which he described the schools of France, Italy, Prussia, Spain, Russia, Sweden, Bavaria, Wurtemberg, Austria, Finland, Norway, Baden, and India, and the curriculum pursued therein. He urged the institution of a school of forestry in Great Britain, and especially suggested that that school should be located at Edinburgh in connection with the new arboretum and with the forests of the Highlands.

Professor Balfour, in moving a vote of thanks to Dr. Brown, commended the plan of an Edinburgh school of forestry, and hoped it would soon be realised.

The motion was agreed to.

Mr. Robert Baxter, forester, Dalkeith Park, read a paper on "Woods for Making different kinds of Charcoal, and the Modes of Preparing it." Almost any kind of wood that grew in this country made, he said, very useful charcoal, with the exception of Poplar, Scotch Elm, Spanish Chestnut, and Lime tree, he did not regard with much favour, owing to their peculiar bark offering great resistance to the charring process. Beech, Plane tree, Ash, Thorn, Oak, Hornbeam, Birch, Alder, and Laurel could all be employed as charcoal producers. The Yew and Holly made very superior charcoal, as they were very heavy, held well together, and had good lasting qualities as fuel. In conclusion, he entered into an elaborate description of the different processes for making the charcoal.

Mr. Malcolm Dunn, the Palace Gardens, Dalkeith, read a paper on "Cryptogamic Plants Injurious to Forest Trees, and their Remedies." Many of this class, he said, were injurious to plant life, and one very important class of diseases amongst trees and timber arose from the attacks of parasitic fungi. He noticed at length instances of attack of a fungus on the roots of *Wellingtonia gigantea*. The spawn of the fungus had completely choked up the sapwood, and thus killed the trees. The fungus had arisen from the decaying roots of old Elm trees which had been allowed to remain in the ground. The remedy for such attacks was the thorough preparation of the ground before planting, the removal of all dead or decaying wood likely to produce fungi, with careful attention to drainage, and timely and judicious prunings and thinnings. When trees were once attacked the best and safest plan was to root them out and burn them, and so prevent the disease spreading to healthy trees.

An interesting discussion followed.

The remainder of the business was of a routine character. *Scotsman*.

Edinburgh Botanical: *November 8*.—The first meeting of the forty-second session of this Society was held on the above date. Sir Wyville Thomson, LL.D., Vice-President, occupied the chair, and delivered the following opening address:—

Although I am happy to be able to say that the

health of your venerable President, Sir Robert Christison, is greatly restored, he does not yet feel it prudent to take an active part in evening meetings. I have accordingly been requested to occupy the chair this evening in his place, and to congratulate you upon the commencement of another session of the Botanical Society. I ought probably under the circumstances to have prepared for you to the best of my ability a general *resumé* of the progress of botanical science during the present year. You are aware, however, that I am greatly occupied with other matters, and have had but little time for preparation; I must therefore ask your indulgence if, instead of attempting to run over the whole range of botany, I direct your attention for the few moments at my disposal to a curious subject of inquiry to which important contributions have been made even since we last met. We are in the habit of teaching that while the differences between living and inert matter are definitely marked, it is difficult, perhaps impossible, to draw a hard-and-fast line between the animal and vegetable kingdoms; but this statement has usually reference to a certain confusion which arises on the border land among a mass of obscure unicellular or very simple organisms, which Ernst Haeckel, the great German innovator, has proposed to raise to the rank of an intermediate kingdom, under the name of the Protista. Between the higher plants and animals the distinction seemed abundantly clear, and to depend not so much upon structure and form as upon fundamental differences in the mode of performance of the most essential vital functions; plants through their protoplasm acting in contact with chlorophyll under the influence of light have the power of shaking asunder the elements of carbonic acid, water, and ammonia, and of recombining their four elements, carbon, oxygen, hydrogen, and nitrogen, into such ternary compounds as starch and cellulose, and such quaternary and higher compounds as albumen. This power, broadly speaking, the animal kingdom does not possess; and thus the vegetable kingdom must be understood to pre-exist the animal kingdom, and to be necessary for the preparation of its food. But in the young and active condition of the vegetable cell there is no chlorophyll present, and no such process takes place. The elements of carbonic acid and water are fixed and recombined in the green leaves of plants, and the more complex products are conveyed in solution in vessels or by endosmosis to the growing points. At these points the cells are multiplying rapidly, but they are entirely pale, and they have no power of performing any true plant functions. In a growing point every cell consists of an external cell-wall of cellulose, an inert ternary compound, enclosing a nucleated mass of protoplasm, or of protoplasm in conjunction with metaplasm, which gives all the manifestations of vital activity which we have in the lowest forms recognised as truly animals. Every living vegetable shell is thus an amœboid rhizopod, enclosed in an external shell of cellulose, a shell which it has been the active agent in secreting. Growth of the plant-shoot goes on, but this growth is produced by the multiplication by fission of the rhizopods, each division enfolding itself in a new cellulose chamber, which we recognise as an additional vegetable cell. During the past year or two some very important observations have brought this aspect of plant life much more prominently before us. Several observers, including Dr. Nitschke, Sir Joseph Hooker, and more especially Mr. Darwin and his son, Mr. Francis Darwin, have worked up carefully the habits and the constitution of the amœboids inhabiting the cells of glandular hairs. In Mr. Darwin's curiously interesting book about *Insectivorous Plants* we have an account of the process by which *Drosera rotundifolia*, the common Sundew, manures itself through its leaves, catches insects, and absorbs and assimilates the nitrogenous matter which they contain. Dr. Nitschke, Mr. Darwin, and others have traced the process fully, and have determined that under the stimulus of a supply of suitable food the cell contents of the cells of the leaf-glands secrete a substance having very much the properties of pepsin, and an acid fluid closely resembling that produced in the stomach of the higher animals during the process of digestion. The hair-glands of *Drosera* infect themselves tightly over a body, such as a piece of bone, which contains the material specially required by the organism, and gradually the angles of the bone are rounded off, and finally the whole is absorbed, and disappears. Of actions such as this *Drosera*, though a strongly marked, is by no means a solitary case. The same properties pertain to many glandular hairs; and within the last few months Mr. Francis Darwin has published some results which bring out still more strongly the close resemblance between the protoplasmic masses contained within active vegetable cells and ordinary rhizopods. The common Teasel, a plant abundant in the woods in some parts of the south of England, has connate leaves—that is to say, leaves which by a soldering of the edges of the leaf-stalks form a cup round the stem. These cups catch the rain-water, and while it is slowly evaporating

insects creep in, and their decomposing bodies shortly make the water slightly putrid. All over the leaves of the Teasel there are scattered minute trichomes, club-shaped glands at the end of short hairs. The clubs consist of an aggregation of a number of cells containing active protoplasm mixed with metaplasm in the form of resin. These glands are abundant in the cups, and at the top of the gland where the little congeries of cells meet, long threads of protoplasm, associated or combined with some of the resin, are thrown out into the water containing a solution of nitrogenous matter. These pseudopodial threads do not apparently pass through any defined openings in the wall of the cell; they seem to pass through it, which is the less surprising as such membranes are well known to be pervious to viscid semi-fluids. When the pseudopodia are brought into contact with any substances greatly required by the economy of the plant, they contract and run into knots and bladder-like expansions, and absorption takes place rapidly, large sarcode aggregations converting the slender threads into chains of bulbous swellings. Mr. Darwin believes that the protrusion of these sarcode filaments may have been originally connected simply with the excretion of resin, but he has fully demonstrated that they now subserve the function of the absorption of decaying animal matter. These observations are extremely curious, but they also seem to me to bear an important practical significance. In coaxing and stimulating and coercing plants to do their utmost to win over from the inorganic kingdom the maximum of food fit for man, we have hitherto been treating them simply as plants, grossly analysing their bodies and their ashes, and supplying in a crude way the material which is necessary to build up the whole fabric. If we are forced to look upon a plant as more emphatically a colony of tolerably independent rhizopods, building a symmetrical zoecium, but building it simply in the sense in which a hydroid zoophite builds its hydroecium, we must do our best to realise the fact that it is with animal functions that we have mainly to do, and that the full development of the plant, which it is our object to secure, depends upon the maintenance of the health and full nutrition of the animals which are building it up. We have learned empirically that certain salts of ammonia and soda are good manures. We are now taught the precise way in which these manures act. These substances, which contain the materials necessary for the life of the protoplasm are supplied to plants by Nature in too small quantity. On the other hand, water and carbonic acid, the chief materials of their habitation, are usually supplied abundantly. The moment a particle of one of the desired salts is brought into contact with the contents of one of the cells the whole series are stimulated, the matter is rapidly absorbed, and the portion of the plant to which the material has been supplied, or by absorption this whole plant, takes on a more vigorous and hearty aspect. The rhizopods, amply supplied with their proper food, multiply freely, and rapidly attain their full size; at the same time they develop more fully their protecting cell-walls, and the plant grows vigorously.

On the motion of Professor Balfour a vote of thanks was given to the Chairman for his address.

The following communications were read:—

I. Obituary notices of deceased members, prepared by Professor Balfour and Mr. F. M. Webb.

The following are among the names of those whom the Society has lost during the past session:—Professor Alexander Braun, Berlin; Professor Hofmeister, Tübingen; Professor Parlato, Florence; Dr. Hugh Algeron Weddell, Poictiers.

II. On Fossil Lichens. By W. Lauder Lindsay, M.D., F.L.S., F.R.S.E.

III. Note on a New Species of Agaric (*Agaricus Sadleri* of Berkeley, M.S.). By Mr. John Sadler.

IV. Miscellaneous Notices.—I. A note was read from Rev. David Landsborough giving an account of a plant of *Edwardia microphylla* at present growing in the open air at Kilmarnock, where it has stood for several years without any protection, and is now 3½ feet in height. He also reports that a plant of *Dicksonia antarctica* is growing to perfection in the open air at Corrie, in Arran, where it was planted some years ago.

2. Dr. Balfour exhibited dried specimens of Indian Pandani which he had received from Dr. King, Calcutta. He also exhibited branches of Sea-Buckthorn covered with ripe fruit, and reported that the plant had fruited abundantly this season on the shore at Tynninghame.

4. Mr. W. Evans exhibited specimens of *Trichomanes radicans* which he had collected last summer on Torc Mountain, Killarney.

5. Mr. W. P. Drummond exhibited fully expanded Pear blossoms from his garden, near Edinburgh, and stated the late flowering of the Pear was not uncommon this season.

6. Sir P. Murray Threipland exhibited and presented to the museum at the Botanic Garden a cone of *Araucaria imbricata*, which had been pro-

duced this season in his garden at Fingask Castle, Errol.

7. Mr. Sadler exhibited specimens and coloured drawings of *Peziza Adæ*, Sadler, *P. cretaea*, Cooke, and *P. tectoria*, Cooke. The drawings were executed by Dr. M. C. Cooke.

8. Mr. McNab placed on the table flowering plants of two varieties of *Primula capitata*.

Chrysanthemum Shows.—The growers of this indispensable autumn flower at least have no cause for complaining that justice is not done to it, seeing that at the present time quite a plethora of shows are being held in its honour. Unfortunately the majority of the growers, or rather their flowers, were behind time for the earlier exhibitions, and some postponements have in consequence had to be made. However, the flowers that we have seen have been quite up to the mark, though nothing beyond it; and we regret to notice that but slight advance is being made in the production of new varieties. True, the new sorts of recent introduction make their appearance here and there, but nothing absolutely new and of any importance has yet seen shown. The metropolitan Chrysanthemum ball may be said to have been opened on Monday at Blackheath and Lambeth, and to have been continued so far as Brixton and Gravesend on Wednesday, and at Woolwich and Stoke Newington yesterday, Friday. The Woolwich show was postponed from Wednesday to the latter date; and the Wimbledon exhibition has been put off from Wednesday for a fortnight, so late are the generality of the flowers in that district. To-day (Saturday) the Ealing Society's exhibition comes off, and similar displays will be held next week, on Monday in South London, on Tuesday and Wednesday at Hackney, and on Wednesday and Thursday at Kingston and Surbiton. Besides these there are the admirable displays at the Crystal Palace and the Temple Gardens, to say nothing of the various nurseries where this flower is made a speciality.

The LEE AND BLACKHEATH HORTICULTURAL SOCIETY'S show, held on Tuesday and Wednesday last, was a very nice one, and included many other flowers besides Chrysanthemums, and fruit and vegetables. The most noticeable features were the groups of flowering and foliage plants, for which Mr. Hart, of Lee, was 1st, and Mr. R. Hill, gr. to G. Penn, Esq., the Cedars, Lee, a good 2d; and their collections included some good *Odontoglossums*, *Calanthes*, *Poinsettias*, &c. Mr. Hart also gained the highest honours for *Poinsettias* with some very good plants, and again he was placed 1st for six white *Primulas*—Mr. C. Welsh, gr. to Mrs. Read, Blackheath, taking a like prize for dark-flowered specimens. The show of Chrysanthemums was below the average, the plants in this district being apparently very late this season. Among the cut blooms the best were Elaine, in Mr. Osborne's stand of six large-flowered, and Prince Alfred in Mr. F. Hatchett's twelve large-flowered. Mr. Hatchett was 2d for twelve large-flowered, having, among others, a fine example of *Bismarck*. 1st the pot plants Mr. Osborne had a good pyramidal plant of Mr. George Glenny. Mr. W. Green, Padrol Place, taking equal 1st with Mrs. G. Rundle. A good plant of *White Cedro Nulli* gained for Mr. Osborne another 1st in the class for one specimen Pompon. The same exhibitor also took the lead with four standard Pompons, good examples of *Golden Circle*, *Salamon*, *White Cedro Nulli*, &c. In the class for four large flowering standards, Mr. Osborne again came to the front, showing amongst others admirable plants of *George Rundle*, *Prince Alfred*, &c.

The show of hardy fruit was tolerably good, especially the dessert and kitchen Apples shown by Mr. Waterhouse and Mr. Pavey, gr. to W. Watkins, Esq., respectively; and the collection shown by Mr. Osborne. The vegetables and cottagers' classes added much to the interest of the show, although nothing of special merit appeared. The table decorations by Mr. Morley, of Blackheath; the collection of fruit, not for competition, of Mr. H. R. Smith, of Blackheath; and Mr. Hart's miscellaneous group of plants were highly commended.

THE BOROUGH OF LAMBETH AMATEUR CHRYSANTHEMUM SOCIETY'S third annual show, held on the same day at the Lecture Hall, Borough Road, was one of the best arranged that we have seen, and most creditable to the locality—especially when it is considered that the whole of the productions were grown within a mile radius of the "Elephant and Castle." The stands of cut blooms of Japanese Chrysanthemums were admirable, as were also the standard plants of large and Pompon-flowered varieties, Messrs. Wilsner, Fryer, Summers, Ball, and Fill, were the chief prize takers.

THE BRIXTON, STREATHAM, AND CLAPHAM SOCIETY'S show, held on Wednesday and Thursday in the pleasant grounds of a local skating club on Tulse Hill, was a small affair, but very good in its

way. The 1st prize group of six large-flowered plants, contributed by Mr. W. Hall, gr. to S. Stevens, Esq., Tulse Hill, were an admirably grown lot, and perfectly bloomed in the case of specimens of Faust, Mrs. Dixon, and Mrs. G. Rundle, the others being scarcely opened enough. The same exhibitor was also 1st with a neatly grown lot of six Pompons, but all deficient in open flower; one, indeed, had not an open bud on it. The other plants staged call for no comment. Cut blooms were fairly well represented as to numbers, and included a few stands of really high-class flowers. The winner of the 1st prize for twelve large blooms was Mr. J. Lee, gr. to Mr. Tom King (a name once famous in connection with a less refined art than gardening), and an excellent stand of blooms it was, the varieties represented being Princess Alexandra, Prince Alfred, Prince of Wales, Nil Desperandum, Hero of Stoke Newington, Mrs. Brullees, Mrs. G. Rundle, Lady Talfourd, Mrs. Halliburton, Rev. J. Dix, Mrs. Dixon, and Baron Beust. For twenty-four there was also a good competition, and equal 1st prizes were awarded to Mr. W. Hall and Mr. J. Holmes, gr. to G. Storey, Esq., Nightingale Lane. The exhibition included a few small groups of Ferns, stove and greenhouse flowering plants, a capital lot of Primulas, a fair show of fruit, and a first-rate lot of vegetables, amongst which the collection from Mr. Livermore may be singled out for honourable mention.

The GRAVESEND AND NORTH KENT CHRYSANTHEMUM SOCIETY held its annual exhibition in the Milton Hall, Gravesend, and, as a whole, a very good show was got together. Beginning with the cut blooms, we find among the classes for gardeners that for twenty-four incurved blooms. Mr. J. Boulton, gr. to R. A. Gibbons, Esq., Northfleet, came 1st, having amongst others fine blooms of Mrs. George Rundle, General Slade, and Mrs. Dixon; the 2d prize going to Mr. Pendred, gr. to S. C. Umfreville, Esq., Greenhithe, amongst whose exhibit we noted good examples of Novelty, Empress of India, Guernsey Nugget, &c. For twelve incurved blooms the order of the above prizetakers was reversed, Mr. Pendred being 1st, and Mr. Boulton an excellent 2d. In these stands were found good blooms of Jardin des Plantes, Golden John Salter, General Slade, White Globe, &c. For twelve blooms, reflexed, Mr. J. Biggs, The College, Northfleet, came 1st, Garnet and Fair Maid of Guernsey being most noticeable. In the class for twelve bunches of Anemones, Mr. J. Boulton was again 1st, showing fairly good Sidonie, Miss Nightingale, Mr. Astie, &c. Among the amateurs, Mr. Carpenter, Gravesend, had it nearly all his own way, being 1st for twelve incurved, showing Sam Weller, Lady Halford, Prince Alfred, &c.; Mr. W. T. Druck, of Stonebridge, Northfleet, gaining 2d honours with, amongst others, good Golden Beverley, Mrs. Dixon, Mrs. George Rundle, &c. For twelve reflexed, Mr. Carpenter was again 1st, staging good Elaine, Beauté du Nord, &c. Twelve bunches of Anemones gained him another 1st, and twenty-four incurved blooms gained him 2d honours. The cottagers' exhibits of these flowers were certainly above the average, Mr. J. Burdee being fortunate in the classes for twelve large-flowered and for twelve Pompons, being also highly commended for a nice collection not for competition, amongst which were James Salter, Elaine, Prince of Anemones, &c.

Dismissing the cut blooms, and turning attention to the pot plants, Mr. J. Boulton was again to the fore with beautifully trained plants of Mr. George Glenny, Hermione, &c.; Mr. J. Pope, gr. to J. Russel, Esq., coming 2d with good plants. For two plants large-flowered and for four standards Mr. J. Boulton was again premier prizetaker, having good George Rundle, Prince of Wales, Dr. Sharp, &c. Mr. Pope was placed equal 1st in this class, and was also 1st in the class for four standard Pompons, the most noticeable amongst which was Pearl. Mr. Boulton also took the 1st for two standards, showing Mr. George Glenny and Mrs. George Rundle; the 2d falling to Mr. Pepper, gr. to Capt. Sankey, who showed the same varieties. In the class for four dwarf-trained plants Mr. J. Biggs was 1st with good Mr. Estie, Bob, Cedo Nulli, &c. Mr. J. Boulton also gained the 1st for a single specimen plant with Mrs. George Rundle, and for a single pyramid Pompon with a fine plant of Calliope.

Among the amateurs' pot plants Mr. W. T. Dunk gained the 1st for four standards with Venus, Mrs. Dixon, &c.; two plants, dwarf-trained, gained Mr. W. B. Carpenter like honours for good plants of Dr. Sharp and Venus. There were also tolerably good collections of vegetables and fruit, also many "garden designs," worked out with bright coloured Chrysanthemums, which all added interest to the show.

Although we must congratulate the management on making the arrangement good for "effect," yet we must stop there, as a large number of the exhibits had neither the names of the exhibitors attached nor the slightest indication as to which classes they belonged.

NEW DAHLIAS OF 1877.—The notes of the new Dahlias distributed by Mr. Turner last spring may be said to have prepared the way for some account of those sent out by his old friend, and in the kindest sense of the term floricultural rival, Mr. John Keynes. It is to these two famous raisers and cultivators that the floricultural community look for new productions, and on the whole what they put into circulation find much favour with growers.

Of the new varieties put into commerce by Mr. Keynes last spring, Mrs. Drummond, a pale lilac self, and of fine quality when shown as a yearling, has not proved so good as was expected: perhaps the season was not favourable to it. Mrs. John Downie, blush ground, deepening to pale lilac, and heavily edged with rosy purple, was much admired when shown as a seedling, and it has proved a fine constant exhibition variety—a model of what a good Dahlia should be. Mr. Keynes has termed it "a wonderful flower," and in doing so he has not overstated its value. The Hon. Sidney Herbert, while grand in colour, being a self flower, of a rich shaded crimson glow, is yet deficient in outline; it is, however, very constant, and for that reason will be grown. David Saunders is a fine dark Mulberry self in the way of the Rev. Dr. Moffatt, but with a higher centre. This is an improvement that will commend itself to Dahlia exhibitors, for it is a taking flower in an exhibition stand. Perfection of Primroses is of a beautiful primrose glow, and comes slightly edged with rose. It is large in size, but remarkably well built, and has been seen to great advantage in stands during the summer. A very constant and valuable show flower is found in John William Lord, shaded orange-buff, but paler in colour on the surface; it is one of the best and most useful Dahlias of the season. Minnie Bond is an exceedingly pretty and pleasing flower, the ground pale cream, finely laced or edged with rosy purple; but it requires liberal growth to get it into size for the exhibition table, and when in good condition it is really a striking flower. Benjamin Crossland is a flower of which high expectations were formed, but it has proved rather too small this season for exhibition purposes; it is a rich dark purple self of excellent form and substance. Vivid is a soft bright scarlet self that is occasionally a good show flower, but requires cutting-out to get the blooms into proper condition. It bids fair to make a first-rate bedding variety, being dwarf in growth, and throws out its numerous flowers well from the foliage on erect stems. John Wyatt is a grand flower in every respect; it is a finely formed crimson-scarlet self, and too much cannot be said in its favour; it takes a high place in a select list of exhibition varieties. John Fraser is a flower which excited high hopes that have not been realised; it has come coarse, probably owing to the wet season, or more likely still from being overworked at the time of propagating it in the spring; it has a chocolate ground, shaded with purple and buff, and is very novel and distinct. Dauntless is remarkable for its telling colour, being of a rich shaded orange shaded with buff; it is likely to be useful.

Some of the best and most useful fancy Dahlias in cultivation have come out of Salisbury, and it is not surprising that the batch of fancy flowers distributed by Mr. Keynes last spring comprised some thoroughly good things. Hercules, yellow ground, striped and speckled with rich crimson, has proved a great acquisition; it is always ready for show, and is capital in every respect. Tippy Bob is a very useful high centred flower, but wanting in the matter of perfection of outline; colour canary-yellow, with stripes of rose and purple; it is novel in marking, and distinct in character. Monsieur Chauvière is a large back-row flower of a very constant character; lilac ground spotted and striped with dark crimson; it must not be thinned, or the flower will become coarse. Rosette is a lovely flower when caught in proper character, the white ground being handsomely striped with rows of purple; but it is apt to come self-coloured, in which case it is not so good as when the fancy character is well displayed. Lucy Fawcett, straw colour, striped and spotted with rich crimson, is both large in size and constant in character, but lacks outline. Lady Allington, dark scarlet tipped with white, is a

very showy useful flower, and will no doubt be grown for its attractive appearance.

The following selection of thirty-six varieties of show Dahlias represent the cream of the flowers shown at various times during the past summer, omitting those that have not yet been distributed:—Mrs. John Downie, John William Lord, John Wyatt, Canary, Christopher Ridley, Acme of Perfection, Alexander Cramond, Countess of Pembroke, Cremonne, Critterion, Charles Leicester, Edward Purchase, George Goodhall, Henry Walton, Herbert Turner, John McPherson, James Service, John Standish, James Cocker, John Neville Keynes, Julia Wyatt, King of Primroses, Leah, Mrs. Stancomb, Memorial, Mrs. Boston, Queen's Messenger, Queen of Beauties, Samuel Plimsoll, Thomas Goodwin, Vice-President, Willie Eckford, William Lucas, Flora Wyatt, Henry Fiasco, and Monarch, the three last named being fancy flowers shown in the self character. The best twenty-four varieties comprised Hercules, Tippy Bob, Mons. Chauvière, Mrs. Purvis, Peacock, Singularity, Artemus Ward, Butterfly, Carnation, Dolly Varden, Fanny Sturt, Flora Wyatt, Henry Glasscock, Letty Coles, Laura Haslam, Leopardess, Miss Lilly Large, Mrs. Goodwin, Mrs. Saunders, Pauline, Prospero, Queen Mab, The Rev. J. B. M. Camm, and Viceroy. R. D.

PLANT PORTRAITS.

ADIANTUM EDGORTHII, Hook, *Illustration Horticolæ*, t. 286.—An elegant little Fern, with slender linear fronds, having brownish-black rachides, and midribiate-oblong pinnae, represented as small wedge-shaped, and toothed along the free edge, in the figure. The fronds are occasionally proliferous, producing little buds or tufts of secondary fronds. Native of Mooltan, where it was discovered by Mr. Edgeworth.

ÆCHMEA VEITCHII, *Botanical Magazine*, t. 6329.—A noble Bromeliad with tufted leaves, leathery in texture, broadly strap-shaped, spotted and minutely serrulate. The inflorescence is a dense spike of scarlet toothed bracts, closely investing flowers of a similar colour. It was discovered in New Grenada by Mr. Wallis, and was introduced into cultivation by Messrs. Veitch.

BEGONIA ROYAL STANDARD, *Floral Magazine*, t. 281.—A seedling raised by Messrs. J. Laing & Co., Stanstead Park, Forest Hill, S.E. The flowers are bold in form, of a rich crimson-lake colour.

BOLLEA LALINDEI, *Botanical Magazine*, t. 6331.—Originally described by Professor Reichenbach, *Gardeners' Chronicle*, 1874, ii., 33. The present plant, grown by Mr. E. S. Williams, differs in colour from that first described. The sepals are rose-coloured, with straw-coloured tips, the petals also rose-coloured but with white margins. The lip is golden-yellow, its disc marked with several elevated ridges.

CALCEOLARIA LOBATA, *Botanical Magazine*, t. 6330.—An herbaceous species, with palmately lobed leaves, like those of a Gooseberry, and erect loosely-branched cymes of yellow flowers, the lip being curiously folded on itself, and spotted on the inner surface. Introduced by Messrs. Veitch.

CERASUS SERRATIFOLIA ROSEA, *Revue Horticolæ*, October 16, 1877 (also known as C. Sieboldii rubra).—A very beautiful, hardy, free-flowering, double-flowered Cherry; the outer petals of a pink colour.

DOUBLE-FLOWERED MIMULUS, *Florist*, November, 1877.—Three varieties are figured, Galatea, Crown Prince, Spotted Gem. All are remarkable for size, form, richness of colouring and spotting, the stamens, moreover, in some cases being replaced by petals. These fine novelties were raised by Messrs. E. G. Henderson & Co., of the Pine-apple Nursery.

DRACÆNA REFLEXA, *Botanical Magazine*, t. 6327.—A very old plant in gardens, but not previously figured save in Redoubt's *Liliacæa*. The leaves are lanceolate-sessile, the flowers very numerous in a handsome branching raceme, each nearly 1 inch long, greenish-yellow, with a short tube and narrow spreading segments. Native of tropical Africa, Mauritius, &c. The figure was taken from a plant which flowered in the Succulent-house at Kew.

HYACINTH QUEEN OF LILACS, *Florist*, November, 1877.—A single flowered variety with pale lilac bells, figured from the collection of Messrs. Veitch.

IXORA FORMOSA, *Floral Magazine*, t. 284.—A fine variety raised by Mr. John Fraser, of Lea Bridge, from javanica, crossed with coccinea, or some other

species (*sic!*). It is a fine variety, with compact trusses of novel colour.

LARKSPUR EARL OF VERULAM, *Floral Magazine*, t. 285.—A very dwarf form of dense compact habit, leaves deeply cut into linear segments and erect dense spikes of flowers. The guard petals are bright ultramarine, the other petals violet-purple. Sander & Co., St. Alban's.

MALUS CORONARIA, *Revue Horticole*, November, 1877.—A North American species with shining leaves, more or less lobed, flowers small, rose-coloured, anthers yellowish.

NEW HYBRID CAPE PELARGONIUMS, *Floral Magazine*, t. 282: **Rosy Morn**, **Spotted Gem**, **Echinatum**.—The two first-named are presumably hybrids from *Echinatum*, crossed with pollen of one of the nosegay section, and to this is attributed their distinctness of character, variety of colour, and the much finer appearance and stouter build of the flower.

TOVARIA OLERACEA, Baker, *Bot. Mag.*, t. 6313.—In accordance with the rule of priority the name *Tovaria* is here adopted instead of *Smilacina*. The present plant is a native of Sikkim Himalaya, at a great height, and is quite hardy here. The stem is 6 feet in height, with broad ovate-oblong puberulous leaves and terminal panicles of whitish flowers, tinged with pink, in form and size not unlike those of a Lily of the Valley. It was introduced into cultivation at Kew, by Dr. Treutler, and flowered in June. The young flower-heads form an excellent vegetable in Sikkim, hence the specific name.

TYDEA MONSIEUR THIERS, *Illustration Horticole*, t. 287.—A handsome Gesneriad, with large, ovate, downy leaves, and panicles of long-stalked, pendulous, Gloxinia-like flowers of a red colour; the lobes of the corolla spotted; the interior of the tube is of a whitish hue. It is said to be a cross between *Tydea Cecilæ* as the seed parent, and *Sciadocalyx Luciani* as the pollen parent.

VANDA CÆRULESCENS var. BOXALLII, *Botanical Magazine*, t. 6328.—A form with sepals and petals pale violet, the lip dark violet, with raised white lines. See *Rechb. f. in Gardeners' Chronicle*, 1877, l, p. 749. Low, Clapton.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, NOV. 14, 1877.

MONTH AND DAY.	BAROMETER.		TEMPERATURE OF THE AIR.				Hygrometrical Deductions from Glaisher's Tables 6th Edition.	WIND.	RAINFALL.

Nov. 8.—A very fine bright day. Little fog in morning. Overcast at eight. Mild.
 — 9.—Overcast, dull and wet till 9 P.M. Fine and bright after.
 — 10.—Fine, but dull and showery at times. Strong wind. Thunder and lightning, accompanied with hail at about 5 A.M.
 — 11.—Overcast, dull and very wet throughout. A violent gale of wind. The heaviest gusts occurred just before midnight, being about the time of the lowest reading of the barometer. The direction of the wind at this time was S.S.W., after which it veered to the West. A day of bad weather.

Nov. 12.—Fine day, frequently dull and showery. Cold. Heavy rain and strong gale in early morning. The barometer read at midnight 28.912 inches.
 — 13.—A fine day. Cold, cloudy, and gloomy in morning. Barometer reading at 9 A.M., 29.145 inches; 3 P.M., 29.335; midnight, 29.624.
 — 14.—A very fine clear day. Cold. Thick fog in morning. Barometer reading at 9 A.M., 29.907 inches; 3 P.M., 30.001; at midnight, 30.067.

LONDON: Barometer.—During the week ending Saturday, November 10, in the neighbourhood of London the reading of the barometer at the level of the sea decreased from 30.14 inches at the beginning of the week to 29.76 inches by the evening of the 4th, increased to 29.86 inches by the evening of the 5th, decreased to 29.63 inches by the morning of the 7th, increased to 29.88 inches by noon on the 8th, decreased to 29.37 inches by the afternoon of the 10th, and was 29.43 inches at the end of the week. The mean reading for the week at sea level was 29.70 inches, being 0.36 inch above that of the preceding week, and 0.30 inch below the average.

Temperature.—The highest temperatures of the air observed by day varied from 60° on the 5th to 54½° on the 4th; the mean value for the week was 57½°. The lowest temperatures of the air observed by night ranged between 36½° on the 4th and 50° on the 7th; the mean for the week was 45½°. The mean daily range of temperature in the week was 12°, the greatest range in the day being 18¼° on the 4th, and the least 8½° on the 7th.

The mean daily temperatures of the air were as follows:—4th, 46.5; 5th, 52.6; 6th, 54; 7th, 53.6; 8th, 50.8; 9th, 51.7; 10th, 49.5, and the departures in excess of their respective averages were 0°.9, 7°.2, 8°.9, 8°.9, 6°.5, 7°.8, and 6°. The mean temperature of the air for the week was 51¼°, being 6½° above the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 110¼° on the 5th, and 104¼° on the 8th; on the 6th the reading did not rise above 60°. The lowest readings of a thermometer on grass, with its bulb exposed to the sky were 24½° on the 4th, and 41° both on the 5th and 8th. The mean value for the week was 40½°.

Wind.—The direction of the wind was S.S.W., and its strength strong. The weather during the week was generally dull and wet, but very mild. A slight thunderstorm occurred accompanied with hail and heavy rain on the morning of Saturday the 10th inst.

Rain fell on five days during the week, the amount collected was 0.81 inch.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 62° at Sunderland, 60½° at Sheffield, and 60° at Blackheath; the highest temperature of the air at Bradford was 56½°, and at Brighton, Wolverhampton, Liverpool, and Hull was 57°; the mean value from all stations was 58½°. The lowest temperatures of the air observed by night were 30¼° at Nottingham, 32¼° at Wolverhampton, and 34¼° at Cambridge; the lowest temperature at Liverpool and Bradford was 43°, and at Plymouth 42°; the mean value from all stations was 37½°. The range of temperature in the week was the greatest at Nottingham, 28¼°, and the least at Bradford, 13½°; the mean range of temperature from all stations was 21°.

The mean of the seven high day temperatures was the highest at Blackheath, Truro, and Sunderland, all 57½°, and at Portsmouth, Plymouth, and Bristol, all 56½°, and the lowest at Wolverhampton, 52½°, and at Bradford, 53°; the general mean from all stations was 55½°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 39°, and at Nottingham, 40¼°; and the highest at Portsmouth, 48¼°, and at Brighton, 48°; the mean value from all stations was 44½°. The mean daily range of temperature in the week was the least at Brighton, 7½°, and the greatest at Nottingham, 14½°; the mean daily range from all stations was 11°.

The mean temperature of the air for the week from all stations was 49¼°, being 10° higher than the value for the corresponding week in 1876. The highest were 51½° at Portsmouth, 51¼° at Blackheath, and 51° at Brighton and Plymouth, and the lowest were 45° at Wolverhampton, and 47° at Nottingham.

Rain fell on every day in the week at most stations, and generally on five or six days. The amounts measured varied from 1 inch and four-tenths at both Brighton and Eccles, and 1½ inch at Truro, to one-tenth of an inch at Sunderland. The average fall over the country was three-quarters of an inch.

The weather during the week was generally dull and wet, but very mild. Thunderstorms occurred generally on the 9th and 10th inst. A solar halo was seen at Bristol on the 7th inst.

SCOTLAND: Temperature.—The highest temperatures of the air varied from 62° at Paisley to 53° at Glasgow, Dundee, and Greenock; the mean value from all stations was 55°. The lowest temperatures of the air varied from 38° at both Edinburgh and Dundee to 42½° at Glasgow; the mean from all stations was 40°. The mean range of temperature

from all stations was 15°. The mean temperature of the air for the week from all stations was 47½°, being 10½° higher than the value for the corresponding week in 1876. The highest was 49°, at Leith, and the lowest 47¼°, at Aberdeen.

Rain fell at Greenock and Paisley to the amounts of 3½ inches and 3¼ inches respectively, whilst at Aberdeen only a quarter of an inch fell. The average fall over the country was 1 inch and four-tenths.

DUBLIN.—The highest temperature of the air was 57°, the lowest 35°, the range 22°, the mean 48½°, and the fall of rain three-quarters of an inch.

JAMES GLAISHER.

Variorum.

HINTS ON CHIMNEY CLEANING.—No hard and fast rule can be laid down as to the length of time that any chimney will go before it requires sweeping. So many things have to be taken into consideration; much depends upon the size of the chimney, the extent of the fire used, and the nature of the fuel. A kitchen fire being used daily, the kitchen chimney requires sweeping every three or four months. Should it smoke, it is a pretty sure sign that the sweep is necessary; for though the chimney itself may be clean enough, the chimney-pot may have become choked up in some way or other that prevents the smoke having free egress. All other chimneys should at least be swept once a-year; and, considering that now-a-days drawing-room fires have sometimes to be lighted during the summer months, twice a-year is by far the safer plan. At the time of the sweep's visits, all small articles should be removed from the rooms, pictures and curtains taken down, and this opportunity should be seized for taking up the carpets. In country places, where a difficulty exists in obtaining the services of a chimney-sweep, persons often clean their own flues in the following manner:—After the fires are out at night the grate is cleared from cinders and ashes, in order that the soot (which is very valuable for gardens) may not be mixed with them. A garden mat, or other convenient material, is then fixed against the front of the mantelpiece, in the same way that it would be by the sweep. The gardener, or any available man, then passes a gun up the chimney as high as he can reach from the left-hand side, removing the mat only just enough to admit his right arm, and holding the mat close with the other. As soon as the soot is settled, and the gun re-loaded (of course with powder only), the operation should be repeated, two discharges of the gun being generally sufficient. The mat must remain safely secured against the chimney-piece all night, and in the morning a man should ascend to the roof and sweep down as far as he can reach. For this purpose a long stick should be procured, to the end of which an old broom, or, better still, a bush or furze, should be attached. *Cassell's "Domestic Dictionary" for November.*

APPLES: A. H. P. The fruits you have sent to us we do not know, excepting that called Gold Acre, which is the true Costard. Severn Bank, Lamb Apple, and British Pippin, are all good sorts, but not superior to others already well known.

ASTILBE BARBATA, &c.—*J. Bryant*. Pot the Astilbes without cutting the roots at all if you can help it. After flowering plant them out on a rich border. Don't prune the *Marchal Niel* at all, except it be to thin out the shoots. We should think the best book you can have to begin with would be an elementary one like *Paxton's Cottager's Calendar*.

HEATING: J. W. W. A small gas stove or one of the several little oil stoves now advertised would answer your purpose.

NAMES OF FRUITS: J. T. P. Apple: *Pomme violette*.—*Ferrystone*, 2, King of the Pippins; 3, Fearn's Pippin; 5, Margil, probably; others not known.—*H. A. B.* 3, Yorkshire Greening; others so rubbishy that they can't be recognised.—*F. Clarke*, 1, Sops of Wine; 3, Longville's Kernel; 4, Loodon Pippin; others not known.—*B. G.*, *Whitehaven*. Pear: Jersey Gratioli. Apples: 1, King of the Pippins; 3, Emperor Alexander.—*W. T.* Apple: King Harry.

NAMES OF PLANTS: Redwood. *Helianthus strumosus* var.—*A. G.* 1, *Begonia* (?), flowers required for identification; 3 and 4, Cactuses, which it is impossible to name in the condition sent; 5, *Euonymus japonicus variegatus*; one of the two others sent without numbers is a *Kleinia*, the other *Isoloma Deppeana*.—*J. Lemon*. *Browallia viscosa*.—*T. T.* Your plant may be *Dendrobium cumulatum*, but it reached us in such condition that we cannot determine it for certain.—*C. B.* *Cotoneaster affinis*.—*T. K. K.* 1, *Aster hortensis*; 2, *Cotoneaster Simonsi*; 3, *Escallonia macrantha*.—*P. T. N.* *Heeria rosea* of Triana, or *Heterocentrum mexicanum* of Hooker.

* Barometer reading, November 11, 9 A.M., 29.169 in.; 3 P.M., 28.928; 10 P.M., 28.625; 10.30 P.M., 28.613; 11 P.M., 28.591; 11.20 P.M., 28.567; 11.30 P.M., 28.557; 11.40 P.M., 28.549 (lowest); 11.45 P.M., 28.554; 11.50 P.M., 28.569; 11.55 P.M., 28.571; midnight, 28.566. Nov. 12, 6.5 A.M., 28.565; 1 A.M., 28.608; 4.30 A.M., 28.617; 8 A.M., 28.772; 9 A.M., 28.788; 11 A.M., 28.835; 0.00, 28.836.

PARONYCHIA TEA, p. 594.—In addition to *P. argentea* *P. nivea* is also used.

PLANT CULTURE: *J. H. T.* Palms will grow in almost any description of soil, either peat or loam; but where good loam of a rich, somewhat adhesive nature, similar to what is found in most parts of Kent, can be had, it is best to grow *Cocos Weddelliana* and others. Drain the pots well, but do not put so much sand in the soil as usual for the generality of other plants; do not over-pot, and give abundance of water in the growing season, never letting the soil even during the winter get nearly so dry as with most things. The above treatment holds good for Palms collectively. *Aspidistra lurida variegata* is an easily grown plant, but although all but hardy in most parts of the kingdom it does much the best when it can have a little warmth; it will do in either peat or loam, but we have found that the leaves usually come with more white in them when loam is used than peat; add one-sixth or a seventh of sand. *T. B.*

VINES SHANKING: *A. L., Oxford.* Yes; we would advise you to do as you say with the outside borders. Make the outside border wider, and not exceeding 3 feet in depth, but well drained. The inside border you need not trouble about, except to have it well watered.

ERRATUM.—In the article on the remains of Egyptian plants, at p. 563, twelve lines from the bottom, for "inhabitants" read "plants."

Markets.

COVENT GARDEN, November 15.

There is a general depression in all parts of our market, and prices are, with few exceptions, lower. A good supply of Grapes is still to hand, at previous rates. The first direct cargo of St. Michael Pines has arrived in very good condition, realising fair prices. Cobs are stagnant, good samples on offer at reduced rates failing to meet with buyers. *James Webber, Wholesale Apple Market.*

SEEDS.

LONDON: *Nov. 14.*—More inquiry is now shown for Clover seeds, and there are indications that the stagnation of the past few months will shortly be succeeded by a moderate amount of activity. Red Clover, it is generally considered, has seen its lowest; and, in consequence of this opinion, there is greater disposition to purchase. Mail advices describe the supplies on the chief American markets as scarcely equal to the home demand. Although the crop is undoubtedly a good one, the Western farmers, not being pleased with current rates, and feeling assured that the expected orders from Europe must shortly enhance prices, will not yet thresh freely; at present, however, there seems no immediate chance of their wishes in this respect being fulfilled; for, taking quality into account, French seed is certainly cheaper than American. New English red does not yet appear in quantity; a few samples have been exhibited on Mark Lane, but no values have yet been fixed. There has been a little business doing in Alsike, and one of two parcels of new home-grown have changed hands. White Clovers and Trefoils are held with firmness. As regards Mustard seed prices have lately gone continuously in favour of buyers; the crop in Cambridgeshire has proved unusually large. Essex seed this year was of extremely fine quality. Good useful brown samples are now obtainable on reasonable terms. In Canary seed there has been rather more doing at the late decline; indeed, quotations are now so low that some little speculation in the article has sprung up. Blue Peas command a good sale at full rates. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

Trade at Mark Lane on Monday was dull in the extreme, and as regards Wheat and flour still weaker prices prevailed. The chief incident was a reduction of 4s. in the price of town-made flour, 52s. per sack being the top price. In wheat transactions occurred at from 1s. to 2s. decline. This, however, does not apply to white produce, the better qualities of which were usually held for the full rates of the previous Monday. The depression in the market may be partly ascribed to the heavy arrivals. Barley was steady in tone, without much doing. Malt was slow, and much the same in price. Oats and Maize, Beans and Peas, all experienced a dragging sale, but quotations generally were no flatter. Flour of the various kinds and grades found very few buyers, even at reduced currencies.—On Wednesday there was no improvement observable in the market, indeed the tendency was towards increased depression. Wheat and flour could only be sold at less money, and holders as a rule were most anxious to realise. Barley was steady; Oats and Maize were much the same as on Monday; and though Beans and Peas were unaltered in value, yet the inquiry was particularly dull. The top price of town-made flour was 50s. per sack.—Average prices of corn for the week ending November 10:—Wheat, 52s. 5d.; Barley, 43s. 3d.; Oats, 24s. 6d. For the corresponding week last year:—Wheat, 48s. 3d.; Barley, 39s. 3d.; Oats, 25s. 10d.

CATTLE.

At Copenhagen Fields on Monday the supply of beasts was about the same as on the previous Monday, but the average quality was scarcely so good. Being scarce choicest qualities in a few instances exceeded our top quotations. The trade in sheep was brisk, and a fair clearance was effected at fully late rates. There were very few calves on offer, and choice qualities were in demand. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 6d. to 6s.; calves, 4s. 8d. to 6s. 2d.; sheep, 5s. 6d. to 6s., and 6s. 6d. to 7s.; pigs, 4s. to 5s.—Thursday's trade was quiet, and without special feature. Both beasts and sheep changed hands quietly, and whilst the best breeds were tolerably steady, other sorts were irregular in value. Calves were firm, and the best kinds rather dearer. Pigs were dull and weak.

HAY.

The Whitechapel market report for Tuesday states that with the supply rather considerable and the demand the reverse of active, prices were hardly so good as on the previous Saturday. Prime clover, 100s. to 137s.; inferior, 85s. to 95s.; prime meadow hay, 90s. to 105s.; inferior, 75s. to 85s.; and straw, 44s. to 58s. per load.—On Thursday there was a fair supply of fodder, trade for which was quiet, and prices for straw were somewhat lower. Quotations:—Prime Clover, 100s. to 137s.; inferior, 85s. to 95s.; prime meadow hay, 90s. to 105s.; inferior, 75s. to 85s.; and straw, 44s. to 54s. per load.—Cumberland Market quotations:—Superior meadow hay, 100s. to 110s.; inferior, 80s. to 90s.; superior Clover, 130s. to 136s.; inferior, 90s. to 110s.; and straw, 52s. to 57s. per load.

COALS.

The market was moderately supplied on Monday with house coals, which sold at last quotations. Business on Wednesday was quiet, but at firmer prices than on Monday. Quotations:—Springwell Hartley, 16s. 3d.; Walls End—Hetton, 20s.; Hetton Lyons, 17s. 9d.; Hawthorns, 17s. 9d.; Lambton, 19s. 6d.; South Hetton, 20s.; Tunstall, 17s. 9d.

AVENUE TREES.

PLANE TREES.—Several thousands of the true *Platanus occidentalis*, from 20 to 20 feet high, straight stemmed, stout, and splendidly rooted.

LIMES, 10 to 20 feet high.

POPLAR, canadensis nova, 12 to 20 feet high.

These Trees have been grown expressly for Street and Avenue Planting.

They are to be seen growing at Knap Hill, and are, without question, the finest stock of their kinds to be found in any Nursery in Europe.

ANTHONY WATERER,
KNAP HILL, WOKING, SURREY.

Webb's

The Queen's Seedsmen,
WORDSLEY, STOURBRIDGE.

EXTRACT FROM CARTER'S LIST OF NOVELTIES FOR 1877.

ESCHSCHOLTZIA MANDARIN.

First-class Certificate Royal Horticultural Society.

"ESCHSCHOLTZIA CROCEA MANDARIN.—A distinct variety; the outer side of the petals brilliant scarlet, the inner side rich orange; very brilliant in colour, and most desirable."—*Gardeners' Magazine*, July 7, 1877.

Electros, price 7s.

NEW JAPANESE DIANTHUS, Eastern Queen and Crimson Belle.

"Messrs. James Carter & Co. exhibited cut blooms of two varieties of Dianthus Heddwiggii, named Crimson Belle and Eastern Queen. The size, substance, and richness of the flowers were remarkable. These varieties will be valuable for garden decoration, especially as they have been proved after some years of trial to come quite true from seed."—*The Journal of Horticulture*.

Electros, price 7s.

CARTER'S NEW CARMINE CANDYTUFT.

This splendid novelty is of dwarf compact habit, and the plant presents one mass of vivid carmine bloom. It is most distinct and beautiful—must not be confounded with a flesh-coloured variety lately exhibited by a Continental house.

"CARMINE-FLOWERED CANDYTUFT.—Messrs. Carter & Co. have sent us cut blooms of this Candytuft, which will doubtless be largely grown when better known, its colour being somewhat unusual amongst Candytufts. It is of good habit, and flowers freely in spring and early summer."—*The Gardener*, August 18, 1877.

Electros, price 5s.

CULVERWELL'S TELEGRAPH PEAS.

This is an extraordinary acquisition, the Peas often being so close together as to appear to be forming a double row in the pod. It is likely to be the forerunner of a new type of this indispensable summer vegetable.

From Mr. J. GOODACRE, Head Gardener to the Right Honourable the Earl of Harrington.

"Culverwell's Telegraph Pea is the longest and handsomest Pea grown, very productive, and excellent quality; a vigorous constitution; quite free from mildew; just the Pea for exhibition."

Electros, price 7s.

For further particulars and other Novelties see above List, now in the Press.

Several Prizes of considerable money value will be offered for some of these Novelties at the Preston Show of the Royal Horticultural Society; for particulars see "Novelty List."

HIGH HOLBORN, LONDON, W.C.

LOBELIA PUMILA MAGNIFICA.

This is by far the finest form of Lobelia in cultivation. The habit of the plant resembles the fine-foliated pumila variety, whilst the flowers are of immense size, and of the richest ultramarine-blue colour.

We have carefully selected our stock, and it may be depended upon to come perfectly true from seed.

VICK'S CRITERION TOMATO.

First-class Certificate Royal Horticultural Society.

REPORT OF TRIALS OF TOMATOS AT CHISWICK (Royal Horticultural Society's Gardens).—"Vick's Criterion (New Improved) is a large smooth ovate variety, of a distinct rosy crimson colour; free fruiting."

Electros, price 15s.

CARTER'S CHALLENGER PEAS.

From Mr. WHALLEY, Head Gardener to His Grace the Archbishop of Canterbury.

"Carter's Challenger is the best Pea we have yet grown; it will become a very great favourite, particularly with market gardeners, as it requires no stakes, and grows well; also a very beautiful Pea, fine for exhibition."

Electros, price 10s.

NEW SWEET PEA—VIOLET QUEEN.

It is dwarfier in habit than the other varieties, and the seed is also quite distinct in appearance, the flowers ranging in colour from deep mauve to light violet, suggestive of the beautiful Bougainvillea.

Electros, price 6s.

TWO NEW MELONS. CARTER'S PINE CREAM MELON.

First-class Certificate Royal Horticultural Society.

Distinct in seed, appearance, and flesh.

Electros, price 3s. 6d.

KHIVA MELON.

We think this Melon will be found to be identical with the variety referred to by Captain Burnaby in his *Ride to Khiva*, p. 278, who speaks of the Khiva Melon as follows:—

"The Melons here have a fame which is celebrated all over the East. . . . The taste is so delicious that any one only accustomed to this fruit in Europe would scarcely recognise its relationship with the delicate, highly perfumed Melons of Khiva."

Mr. A. McARTHUR, Head Gardener to H.R.H. Prince Dhuleep Singh.

"Your Khiva Melon is a very good one; it is medium sized, thin skinned, melting and juicy; the flesh is green, very prolific, and quite distinct."

CARTER'S LITTLE WONDER PEAS.

A wrinkled Marrow, as early as Advancer, and quite equal in length and breadth of pods, productiveness, and flavour to G. F. Wilson, or the finest type of Veitch's Perfection.

From the "Gardeners' Chronicle," July 21, 1877.

"Messrs. James Carter & Co. showed a new Pea, named Little Wonder, very dwarf, a great bearer, with the pods large and straight, and Peas of capital flavour."

Electros, price 10s.

Aberdeen Forst Tree Nurseries.

LARCH and SCOTCH FIR (from Native Seed) are grown here on high-lying grounds by the million, of robust growth and abundant root-fibre; also various ages and sizes are grown for sale in similar large proportion of other CONIFERS and TIMBER TREES, FRUIT TREES, ORNAMENTAL TREES and SHRUBS, &c.

The prices are moderate. Special contracts made for large quantities. The cost of Packing saved by truckloads. Quick transport to all parts of the Kingdom or abroad.

Intending Planters are solicited to visit the Nurseries. Stock selected will be reserved, and when required despatched with promptitude. Catalogues free.

BENJAMIN REID AND CO., Nurserymen, Aberdeen, Scotland.

Case, Packing, and Carriage Free to any Railway Station in England and Wales.

Other Collections, for Greenhouse or Conservatory, &c., 12s. 6d., 21s., 42s., 63s., and 84s. each.

From Mr. H. BENNETT, Belle Vue Crescent, Clifton, Bristol. March 10, 1877.

"I am glad to tell you that the Hyacinths, Tulips, and Crocus I had in the Autumn have given entire satisfaction; the flowers are splendid."

From R. PRONOVE, Esq., Bathgate, N.B. February 7, 1877.

"The Bulbs received from you in the Autumn have been particularly fine; some of the Hyacinths and Tulips now in bloom are large and beautiful, and have far exceeded any that I have had before."

DANIELS BROS.,
THE QUEEN'S SEEDSMEN, NORWICH.

Vines for Fruiting and Planting.

JOHN COWAN, The Vineyard, Garston, near Liverpool, begs to state that his stock of Young VINES is this year in splendid condition, and that he is now Booking Orders to be supplied when required. Inspection of the stock is invited.

WALKER AND CO., Farnborough Station, Hants.

AMIES' CHEMICAL MANURE.

USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.

PREPARED IN A FINE, DRY, INODOUROUS POWDER.

Price, £12 per Ton; 15s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.

Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to
AMIES' CHEMICAL MANURE CO. (LIMITED),
79, MARK LANE, LONDON, E.C.

BG L Olicake.
ARRIST YOUR PURCHASES of all other Cake until you have read the "Book of Testimonials" from users of this cake. Sent post-free by the Agent for the County, or by the Makers.
Mills, Shad Thames, London, S.E.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has outwitted many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1d., 3s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (Limited).

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application.
JAS. T. ANDERSON, 149, Commercial Street, Shoreditch, London, E.C.

RUSSIA MATS for Covering from Frost, GUNNY BAGS, from 3½d. each. Delivered free to any station in London.

Roshers Garden Edging Tiles.

THE ABOVE and many other PATTERNS are made in materials of great durability. The plainer sorts are specially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper.

GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design.
F. ROSHER AND CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E.

Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROPAGATING BOXES, also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.

Illustrated Price Lists free by Post. The Trade supplied.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.
WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Stable Paving of great durability, Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety, Stairs, Cement, &c.
F. ROSHER AND CO., Brick and Tile Merchants. See addresses above.

SILVER SAND, fine or coarse grain as desired. Prices by Post per Ton or Truckload, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post.
FLINTS and BRICK BURRS for Rockeries or Ferneries.
KENT PEATS or LOAM supplied at lowest rates in any quantities.

F. ROSHER AND CO.—Addresses see above.

N.B.—Orders promptly executed by Rail or to Wharves.

A Liberal Discount to the Trade.

STEVENS' TRENTHAM GREENHOUSE BOILER, After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER, Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877.
"GENTLEMEN,—In reply to your enquiry as to our opinion of your Stevens' Trentham Boilers, we do not hesitate to pronounce them to be by far the best Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trentham Boiler, and we have now *thirteen* of various sizes at work.
"For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trentham Boilers supplied by you, and we have never felt so little anxiety in connection with our hot-houses during the cold winter months as we do now.
"We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.
"We are, Gentlemen, yours faithfully,
"JAMES VEITCH AND SONS."

For Illustrations, with full particulars apply to the Sole Makers,

F. & J. SILVESTER.

HOT-WATER ENGINEERS, &c., &c.,
Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—in all others being base imitations.

GALVANISED WIRE NETTING.

The undersigned, the INVENTORS and ORIGINAL MANUFACTURERS, beg to give Notice that from this date they have reduced the prices of this article by one-third of the original rates. Delivery free. Stock sizes executed upon receipt of order.

BARNARD, BISHOP & BARNARDS,
NORFOLK IRONWORKS, NORWICH, and 93 and 95, QUEEN VICTORIA STREET, LONDON, E.C.—October 20, 1877.

AN EXTRAORDINARY BOILER.—During the Great Boiler Contest at Birmingham, in 1872, all Boilers were severely tested to prove their respective merits. One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch pipes, and yet had more than 1 bushel of fire drawn from its furnace in the morning—equal, in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners! This was THE CHAMPION, Deards' Patent Close-Coil Boiler, for Drawings and Prices of which send two stamps to Messrs. DEARDS, Boiler Works, Harlow, who now have their Boilers at work in every county of England except three. Amateurs will also find THE WONDER, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Prize Silver Medals.

NOTICE TO THE TRADE.
TEBBS' UNIVERSAL FUMIGATOR
Can be obtained Wholesale of FLANAGAN AND SON, Seedsman, 98, Cheapside, London, E.C.; and of CORRY AND SOFER, Shad Thames, London, S.E.
No one cultivating plants under glass should be without one.

AGRICULTURAL LOCOMOTIVES,
STEAM PLOUGHING MACHINERY,
ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES,
STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,
AVELING & PORTER,
ROCHESTER, KENT; 72, CANNON ST., LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 10-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth pounds of coal per horse-power per hour.

JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz., the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:—

Sizes.			To heat of	Price.
High.	Wide.	Long.	4-in. Pipe.	£ s. d.
20 in.	18 "	15 "	300	7 0 0
20 "	18 "	24 "	400	8 0 0
20 "	18 "	30 "	500	9 0 0
24 "	24 "	24 "	700	12 0 0
24 "	24 "	30 "	850	14 0 0
24 "	24 "	36 "	1,000	16 0 0
24 "	24 "	48 "	1,400	20 0 0
28 "	28 "	60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Batham Hill, S.W., May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS of HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES AND SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.
When ordering Boilers please refer to the above advertisement.

 experience in retail houses. Satisfactory references.—
 G. W., 39, Cochrane Street, St. John's Wood, N.

KINAHAN'S LL WHISKY.
 Universally recommended by the Medical Profession.
 A pure old spirit, mild, mellow, delicious, and most wholesome.
 Dr. Hassall says, "The samples were soft and mellow to the
 taste, aromatic and ethereal to the smell. The Whisky must be
 pronounced to be pure, well-matured, and of very excellent
 quality."—Wholesale: 20, Great Titchfield Street, London, W.

GRATEFUL—COMFORTING.

E P P S ' S
 (BREAKFAST)

JAMES EPPS & CO.,
 HOMŒOPATHIC CHEMISTS.

DINNEFORD'S FLUID MAGNESIA.

The best remedy for ACIDITY of the STOMACH,
 HEARTBURN, HEADACHE, GOUT, and
 INDIGESTION; and the safest aperient for delicate
 Constitutions, Ladies, Children, and Infants.
 DINNEFORD AND CO.,
 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.—The extraordinary
 range of temperature prevailing in our climate is ex-
 tremely trying to the delicate-constituted, the weak and nervous.
 All troubled by these afflictions should resolve to resort to this
 strengthening and regulating Medicine immediately they per-
 ceive in themselves discomfort or that feeling of restlessness
 which betokens Disordered Digestion and Defective Secretion
 of Bile. One of HOLLOWAY'S PILLS taken about noon
 and followed at bed-time by a dose sufficiently large to act
 aperiently will speedily recruit the faulty functions, and restore
 order throughout the whole system. A treatment so safe in
 operation and so successful in result, should be known and
 practised when, from cold and sundry other causes, disease is
 attempting to gain a vexatious footing.

JOHN COWAN,

THE VINEYARD, GARSTON, NEAR LIVERPOOL,

Begs to announce that his Stock of GRAPE VINES, both for Planting in Vineries and Fruiting in Pots, is this season unusually large, well ripened, and altogether in splendid condition.

A NEW DESCRIPTIVE CATALOGUE is now ready, and will be forwarded on application.

The following are amongst the Special Advantages of this Establishment for insuring to intending Purchasers of Grape Vines superior plants, viz. :—An unusually large and healthy stock of parent Vines, grown and tested as to name and quality upon the premises, consequently all are true to name. The cultivation of Vines being made a speciality, they are well-grown and perfectly ripened; and the stock being very large they are offered at very moderate prices.

The following are a few Varieties selected from his Descriptive Catalogue:—

BLACK GRAPES.

BLACK HAMBURGH,
MADRESFIELD COURT (B. MUSCAT),
LADY DOWNE'S SEEDLING,
MRS. PRINCE (B. MUSCAT),
GROS COLMAN,
FRANKENTHAL,
BARBAROSSA,

Strong Clumps of SPIRÆA (Hoteia) JAPONICA, a quantity of LILIUM LANCIFOLIUM in variety, and other choice LILIES, GLADIOLI, selected HYACINTHS for glasses, pots, and borders; TULIPS, CROCUSES, POLYANTHUS, and other BULBS from Holland, together with a fine collection of AMATEUR TULIPS.

MESSRS. PROTHEROE AND MORRIS will sell the above by AUCTION, at the Mart, Tokenhouse Yard, E.C., near the Bank, on MONDAY NEXT, at half-past 7 o'clock punctually.

Catalogues had of the Auctioneers, 98, Gracechurch Street, E.C., and Leytonstone, E.

Important to Amateur Tulip Growers.

MESSRS. PROTHEROE AND MORRIS will include in their SALE of DUTCH FLOWER ROOTS, at the Mart, Tokenhouse Yard, E.C., on MONDAY NEXT, the entire stock of AMATEUR TULIPS the property of Charles Williams, Esq., of Stamford Hill, E., probably the finest and most unique collection extant, also the MAHOGANY CABINETS and FITTINGS. No reserve.

Gospel Park, N.W.

Mansfield Road Nursery, adjoining the Railway Station. SALE of the VALUABLE LEASE, and also the whole of the NURSERY STOCK, in lots to suit the Trade and private buyers, consisting principally of a choice collection of Hardy Alpine and Herbaceous Plants, Evergreen and Coniferous Shrubs, Roses, Fruit Trees, and Two small Greenhouses, &c.

MESSRS. PROTHEROE AND MORRIS are instructed to SELL the above STOCK by AUCTION, without reserve, on the Premises, on FRIDAY, December 14, at 11 for 12 o'clock. The valuable LEASE of the NURSERY, held direct from Lord Mansfield for an unexpired term of 10 years, will be offered on the Premises prior to the Sale of the Stock and Effects. The Nursery occupies an excellent position, and comprises 2 Acres of very fertile Land. Rent £40 per annum. To an experienced Gardener with moderate capital this Sale offers an excellent opportunity.

May be viewed the day prior to the Sale. Catalogues and particulars may be had on the Premises; and of the Auctioneers, 98, Gracechurch Street, E.C.

Dutch Bulbs.

MR. J. C. STEVENS will sell by AUCTION at his Great Rooms, 38, King Street, Covent Garden, W.C., every MONDAY, WEDNESDAY, and SATURDAY during November, consignments of Double and Single HYACINTHS, TULIPS, for glasses, pots, and borders; CROCUSES of all colours; NARCISSES, ANEMONES, SNOWDROPS, GLADIOLI, LILIUMS, and other BULBS arriving weekly from well-known farms in Holland, in large and small lots to suit all buyers.

On view the mornings of Sale, and Catalogues had. N.B.—The Sales each day commence at half-past 12 o'clock precisely, and generally finish about half-past 5 o'clock.

Lageria alba.

MR. J. C. STEVENS will include in his SALE on THURSDAY, November 29, Thirty-six Plants of various sizes of the beautiful LAGERIA ALBA, some of which are in flower, the property of Mr. Howard, Florist, 29, King Street, Covent Garden, W.C.

Auction Rooms and Offices, 38, King Street, Covent Garden, W.C.

Dendrobium bigibbum superbum.

MR. J. C. STEVENS will sell by AUCTION at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, November 29, at half-past 12 o'clock precisely, a splendid consignment of DENDROBIUM BIGIBBUM SUPERBUM, by order of Mr. B. S. Williams, who has much pleasure in offering this hitherto rare and expensive Dendrobe, received from his collector in Torres Straits. It will be seen from the Plants in flower that there is no question about its being the true variety, producing, as it does, bulbs averaging from 12 to 24 inches in length, and flower-spikes producing as many as ten highly-coloured flowers. All the plants here offered are starting freely into growth, and many of them are throwing up spikes from the old bulbs, which it is expected will attain maturity, as some of the plants exhibited in flower are from the same importation. At the same time will be offered sixty fine imported trunks of TODEA SUBERBA, a collection of STOVE and GREENHOUSE PLANTS, &c.

On view the morning of Sale, and Catalogues had.

West Hallam Nurseries, near Derby and Nottingham.

To GENTLEMEN and OTHERS engaged in Planting.

MESSRS. OLIVER, NEWBOLD AND OLIVER beg to announce that they have received instructions from the Executors of the late George Small & Son (of the Ilkeston and West Hallam Nurseries), to SELL by AUCTION, at the Nurseries, West Hallam, on TUESDAY, WEDNESDAY, and THURSDAY, November 27, 28, and 29, at 11 o'clock each day, without the slightest reserve, the magnificent Collection of Specimen CONIFERÆ and other TREES and SHRUBS, including fine-grown Araucaria, Retinospora, Wellingtonia, Cupressus Lawsonii, Cedar of Lebanon, Picea Nordmanniana, Cryptomeria, Irish Yews, Thuopsis borealis, &c., together with two very fine Specimen Weeping Hollies, also Apple, Pear, Plum, and other Fruit Trees. The Auctioneers recommend the above Trees, which are in excellent condition, well rooted, and will lift with large balls of earth.

Catalogues, seven days prior to the Sale, at the Auctioneers' Offices, Wardwick, Derby, and at the Nurseries, West Hallam and Ilkeston.

West Hallam is 3 miles from Ilkeston Station on the Erewash Line of Railway, 9 from Nottingham, 7 from Derby.

Bowdon Nurseries, Bowdon, near Manchester.

GREAT SALE of fine well-grown FOREST TREES, pyramidal and dwarf-topped FRUIT TREES, choice CONIFERÆ, EVERGREENS, FLOWERING SHRUBS, ROSES, &c.

MR. J. WALTON is instructed by Mr. R. Thornhill to SELL by AUCTION, November 28 and 29, at 12 o'clock precisely, the remaining valuable stock of TREES as above. Catalogues now ready.

Wonersh Nursery, near Guildford, Surrey. To NOBLEMEN, GENTLEMEN, CONTRACTORS, and OTHERS.

MR. JOHN BULLEN will sell by AUCTION, on the Premises as above described, on WEDNESDAY and THURSDAY, November 28 and 29, commencing each day punctually at 1 o'clock, by order of Messrs. Virgo & Son, the extensive and well-known Nurserymen and Florists, a well-grown Stock of TREES and SHRUBS, consisting of about 800 Pinus austriaca, 1½ to 8 feet; 40,000 Spanish Chestnuts, 2-yr. seedlings; 40,000 Hazel, 20,000 each of Ash, Alder, and Withy; 20,000 Birch, 4000 Maple, 7 feet; quantity of Scarlet Oak, 400 strong Filberts, 4 feet 6 inches; 400 English Yews, 500 Green Holly, 2000 Hornbeam, 2½ to 3½ feet; a good collection of Ornamental Trees of various heights, Mountain Ash, Laburnum, Welch Elm, Hornbeam, Sycamore; double white, pink and scarlet Thorns; Limes, Poplar, Horse Chestnut, Common Laurels, Portugal Laurels, Green Box, Weymouth Pine, Spruce and Silver Fir, 50,000 strong transplanted Quicks, black and red Currants, variety of trained and standard Apple, Pear and Plum Trees in sorts; quantity of Walnut Trees; several dozen of choice Rose Trees, standards and half-standards.

NOTE.—The whole of the stock is in good condition for removing. Wonersh Nursery is a short distance from Bramley Station, on the Horsham Line, where a conveyance will each day meet the 12 o'clock train.

May be viewed two days prior to the Sale, and Catalogues obtained of Messrs. VIRGO AND SON, Wonersh Nursery; "Grantley Arms," Wonersh; "Jolly Farmer," Bramley; "Albion Hotel," Working Station; "Red House Hotel," Working Station; "King's Arms," Godalming; "Bush Hotel," Farnham; "Queen Hotel," Farnborough; "Talbot Hotel," Ripley; and of the Auctioneer, 50, High Street, Guildford, Surrey.

In Liquidation, re Scott.—Northgate, Chichester.

UNRESERVED SALE OF NURSERY STOCK.

Many thousands of beautifully-grown SHRUBS, in fine condition for removal, consisting of Aucubas, Bays, Laurels, Magnolias, Box, Euonymus, Laurustinus, Phillyrea, Vex, Berberis, Cupressus macrocarpa, and many others. Also fine specimens of CONIFERÆ, ARAUCARIAS, CEDARS, RIGIDAS, ABIES, Golden YEW, THUJA, CUPRESSUS, &c. large Standard LIMES, ELMS, POPLARS, CHESTNUTS; FRUIT TREES of sorts, Gooseberries, Currants, Filberts, Asparagus, Rhubarb; a quantity of STOVE and GREENHOUSE PLANTS; about 1000 PINE PLANTS in all stages of growth, some with ripe fruit, and of the best varieties.

MESSRS. HOBGEN BROTHERS will sell by AUCTION, on the Premises, on THURSDAY and Friday, December 6 and 7, the above well-grown stock of TREES, SHRUBS, &c. Sale to commence each day at 12 o'clock punctually.

May be viewed two days previous to the Sale, and Catalogues obtained on the Premises; at the "Dolphin" Hotel, Petersfield; the "Angel" Hotel, Midhurst; "Sea House Hotel," Worthing; and of the Auctioneers, East Street, Chichester, one week previous to the Sale.

FOR SALE, a FLORIST and NURSERY-MAN'S BUSINESS, under exceptional circumstances. Premises are commandingly situated, with 50 feet frontage to suburban main road, and consist of excellent Dwelling House, Six Greenhouses, hot-water heated, good Shop, &c.; grounds ¼ acre. Rent £46; annual returns £850. Price for goodwill, eleven years' lease, fixtures, utensils, and stock, £375 only. A genuine bargain. Personal applications save time and trouble. GARFORD AND CO., Auctioneers, 13, Bow Lane, Cheapside.

THE CANCER HOSPITAL,

Brompton, and 167, Piccadilly, W. (Free), (founded 1851).—The late Archbishop of Canterbury, in a sermon preached by His Grace on behalf of this Hospital, said—

"There is no disease more pitiable than that to which this institution is specially devoted. From the first symptoms of attack one long course has commonly been prognosticated—a fearful looking-for of a lingering progress towards a death of anguish. Could the greatness of the suffering be laid before you—could you be shown its severity so as to see it in its true proportions and natural colours—no one ended with the feelings of humanity could resist the spectacle; they would think all they possessed a trifling sacrifice, if, at such a price, they could mitigate such misery; and yet they know that these sufferings exist as surely as if they were spread before their eyes. This, therefore, is a case in which I may justly ask your liberal contributions, that the relief afforded by this Hospital may more nearly approach the amount of misery it endeavours to remove."

SUBSCRIPTIONS will be most thankfully received for this Hospital, which is free. Diet required to be most generous, and medicines of the most expensive kind.

Hon. Treasurer—Geo. T. Hertslet, Esq., St. James's Palace, S.W. Bankers—Messrs. Coutts & Co., Strand, W.C. Out-patients' Establishment and Office, 47, Piccadilly (opposite to Bond Street), W. H. J. JUPP, Secretary.

The Nurseries, Bedford Road, Northampton.

For Present Planting or Sowing. CABBAGE PLANTS.—Gee's Superior Early Enfield Market, Drumhead, and Thousand-headed, all at 3s. per 1000; Purple Sprouting BROCCOLI, and BRUSSELS SPROUTS, 5s. per 1000; Winter LETTUCE PLANTS, Brown Cos and Hardy Green, at 7s. 6d. per 1000. Terms cash with order. Gee's noted stocks of Winter ONIONS, CAULIFLOWER, CABBAGE, and all other kinds of Seeds and Plants for present use, of best quality. CATALOGUES on application to FREDK. GEE, Seed and Plant Grower, Nurseryman, &c., Biggleswade, Beds.

MYROBALAN, or CHERRY PLUM, is the best stuff for blending Old Fences or Making New Ones. It grows vigorously in the poorest soils, even where Whitehorn will hardly exist, and bears clipping like Whitehorn. Its stiff hard branches, and dangerous spines or thorns, effectually prevent cattle or evil-disposed persons from getting through Fences made of it. Plant from four to six in a yard. Sizes and prices on application to EWING AND COMPANY, The Royal Norfolk Nurseries, Eaton, near Norwich.

CHEAP OFFER.—Ozothamnus rosmarinifolius, white, useful for cut flowers; Escallonia macrantha, very fine for potting; Cotonaster microphylla; Pyracantha, red-berried; Aristolida Maqui, fine evergreen, with Laurel-like foliage, seldom offered; Santolina chamaecyparissus, white foliage evergreen; Lonicera aurea reticulata, Sambucus aurea variegata, admirable for town gardens; Ribes sanguinea. All the above at 2s. per dozen, 15s. per 100. Laurustinus, common, shining and black-leaved, 7s. 6d. per 100, 60s. per 1000. WILLIAM ABRAHAM, Nurseryman, Limerick.

BEAUTY OF HEBRON POTATO.—This new American sort is now offered for the first time. This valuable Potato originated in 1874 from seed bulbs of the Chili Rose. The vines and leaves strongly resemble those of the Early Rose, only more vigorous. The plants appear above-ground very shortly after planting, and from that time continue to grow with great rapidity, outstripping all other varieties in strength of growth and luxuriance of foliage. On this account it will be understood they withstand better the ravages of the Colorado Potato Beetle than any other Potato yet brought before the public. The tubers, shape like those of the Early Rose, are very smooth, slightly tinged with pink around the eyes, but attain a pure white colour during the winter. Their yield is really enormous. The tubers lying closely together in the hills, the labour of digging them is but slight. In point of earliness it may be ranked as ripening at least twelve days earlier than the Snowflake, and no less than three or four days ahead of the Early Rose. For culinary purposes its mealiness, quality, and richness and delicacy of flavour give it a precedence before all other varieties. Contrary to what is usually the case in all large specimens of Potatos the Beauty of Hebron almost invariably prove sound and solid to the core. May be obtained of the principal Seedsmen of England. J. M. THORBURN AND CO., 15, John Street, New York U.S.A.

CHARLES B. SAUNDERS, Caesarian Nurseries, St. Saviour's, Jersey, respectfully solicits Orders for the following NURSERY STOCK:— ELMS, 2000 Guernsey, fine upright trees, 7 to 12 feet, 30s. to 100s. per 100. OAKS, 5000 Evergreen, carefully grown, 8 inches to 8 feet, 8s to 150s. per 100. EUONYMUS, 10,000 Golden, Green, and Silver, 8 inches to 2 feet, 12s. 6d. to 50s. per 100. BULBS, CAMELLIA STOCKS, CARNATIONS and PICOTÉES, FRUIT and FOREST TREES, SHRUBS, &c. CATALOGUES of which may be obtained on application.

Kent—The Garden of England. THOS. BUNYARD AND SONS offer the finest Stock in the Trade of 10,000 Standard CHERRIES, 15,000 Standard PEARS, 1,000 Standard MULBERRIES, KENT COB NUTS, and other FRUIT TREES. Prices of which may be found in their Trade LIST, just published. Also cheap and fine AUCUBAS, 2 to 6 feet; trained PLUMS and PEARS, RHODODENDRON PONTICUM, SPRUCE, large, YUCCAS, ELMS, LIMES, and other FOREST TREES, CLIMBERS, &c. THOS. BUNYARD AND SONS, The Old Nurseries, Maidstone, Kent.

Fruit and Forest Trees, Ornamental Shrubs, SEEDS, &c. J. SCOTT, The Royal Nurseries, Merriott, Somerset, has to offer large and fine Collections of the above, in large quantities, and at moderate prices; all are in excellent health and well rooted. The "ORCHARDIST," price 3s. 6d. The best work on Fruit Trees and their cultivation in the English language.

STOTT'S MONARCH RHUBARB.—The stems grow to an enormous size, and are of a fine Gooseberry flavour. From the Canadian "Weekly Globe." "Shirley Hibberd says that one who wants a Rhubarb that makes leaves as big as a dining table, or stems as thick as a Cedar Tree, that rise as high as a tall human dwarf, should order Stott's Monarch at once. After being at sea for three years as to the whereabouts of this wonderful Rhubarb, he has at last discovered that it is to be obtained from Stuart & Mein, Kelso." Roots 1s. 6d. each. STUART, MEIN AND ALLAN, Nurserymen and Seedsmen, Kelso.

AMERICAN BLACKBERRY CUTTINGS, of the Kittatany variety.—A few hundred specimen cuttings of this celebrated American Berry have been imported by the subscribers from New England, and will be sold at 15s. per dozen. Post-office order to accompany. They will be carefully packed and delivered at any railway station in Liverpool. An Illustrated Descriptive CIRCULAR sent on application with postage stamps. D. C. LOWBER, 35, Chapel Walks, Liverpool.

To the Trade. MESSRS. LEVASSEUR AND SON, NURSERYMEN, Ussy, Calvados, France, have an immense stock of Seedling FOREST TREES, Hardy Conifers, and other SHRUBS, for transplanting and transplanted; several millions of 1-year THORN. Priced CATALOGUES may be had of Messrs. R. SILBERRAD AND SON, 5, Harp Lane, Great Tower Street, London, E.C.

MESSRS. CHARLES LEE & SON,
ROYAL VINEYARD NURSERY, HAMMERSMITH,
LONDON, W.,

HAVE MUCH PLEASURE TO OFFER THE FOLLOWING VERY

BEAUTIFUL AND INTERESTING NEW FRUITS,

Now offered by them for the first time:—

RUSSIAN TRANSPARENT APPLE.

In the *Journal of Horticulture*, December 21, 1876, "J., Lincolnshire," describes this valuable Apple as giving a "never-failing crop," and as being "a rent-paying tree" for cottage gardens. Mr. BEULAH, an experienced Lincolnshire Orchardist, confirmed this evidence of the usefulness and profitableness of this much neglected but desirable Apple.

A Tree that bears a never-failing crop, of excellent quality, as stated below by Dr. HOGG, must be as near perfection as possible, and a desideratum that cannot fail to be appreciated by Orchardists in general. The Russian Transparent Apple was brought from Moscow during Napoleon's campaign in Russia, by General Boucheret, who, noticing its hardiness and free growth, and believing it would be suitable for English gardens, brought a quantity of grafts to his home in North Lincolnshire, round which it became and has remained up to this time localised; and now, through the kindness of Mr. Beulah, we have been enabled to purchase all the available grafts from the original stock.

The following is from Dr. HOGG's description:—

"Fruit large, roundish, somewhat oblate, narrowing towards the crown, where it terminates in several prominent ridges, flat at base; skin smooth and shining, grass-green, strewed with large russet dots. Eye closed. Flesh very tender and juicy, with a pleasant sub-acid flavour, and a peculiar and agreeable aroma. I am convinced that this is one of the most valuable culinary Apples in cultivation, and is worthy of more than local fame."

MESSRS. CHARLES LEE AND SON have much confidence in introducing this desirable and profitable Apple to more extended cultivation.

Strong Maiden Plants now ready, price 7s. 6d. each.

HENSON'S SEEDLING GOOSEBERRY.

This excellent variety was figured in the *Florist and Pomologist* for May, 1874, a First-class Certificate having been awarded to it by the Fruit Committee of the Royal Horticultural Society in 1873. It was described as "a new and distinct variety of exceedingly good quality, of the hairy red section, and a good dessert fruit of medium size."

MESSRS. CHARLES LEE AND SON having purchased the entire Stock of this valuable Gooseberry, they are now prepared to distribute it to the Public.

Price per Plant, 3s. 6d.

THE USUAL DISCOUNT TO THE TRADE.

NEAPOLITAN ONION SEED.

NEAPOLITAN GIANT ROCCA

NEAPOLITAN GIANT EARLY WHITE TRIPOLI

NEAPOLITAN GIANT LATER WHITE TRIPOLI

NEAPOLITAN MARZAJOLA WHITE

NEAPOLITAN NEW QUEEN.

G. V. DE LUCA

Has all the above well-known varieties of these deservedly esteemed Onions
now in Stock and ready for immediate delivery.

Price on application. Special Quotation for Quantities.

See *Gardeners' Chronicle*, January 20, 1877.

G. V. DE LUCA, 5, GUILDHALL CHAMBERS, BASINGHALL STREET, LONDON, E.C.

IMPORTANT.

We, the undersigned, certify that all the above varieties of Onion Seed have been carefully
tried by us, with a good result, especially the Giant Rocca, which proved excellent growths.

(Signed), W. ROLLISSON AND SONS, The Nurseries, Tooting, S.W.

IMPORTANT SALE.

DENDROBIUM BIGIBBUM SUPERBUM.

MR. J. C. STEVENS will SELL by AUCTION, at his Great
Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, November 29,
at half-past 12 o'Clock precisely, a splendid Consignment of DENDROBIUM BIGIBBUM
SUPERBUM, by order of Mr. B. S. WILLIAMS, who has much pleasure in offering this hitherto
rare and expensive Dendrobe, received from his Collector in Torres Straits. It will be seen from
the plants in flower that there is no question about its being the true variety, producing, as it does,
bulbs averaging from 12 to 24 inches in length, and flower-spikes producing as many as ten
highly-coloured flowers. All the plants here offered are starting freely into growth, and many of
them are throwing up spikes from the old bulbs, which it is expected will attain maturity, as some
of the plants exhibited in flower are from the same importation.

On view the morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN,
LONDON, W.C.

NEW PEA, "CRITERION" (Standish).

JAMES VEITCH & SONS

DESIRE TO DIRECT ATTENTION TO

THIS EXCEEDINGLY FINE NEW MAIN CROP PEA.

It is one of several seedlings raised by the late Mr. John Standish, who for some years devoted much attention to hybridising and improving the quality of this vegetable, and from whose Executors J. V. & Sons have purchased the whole stock of his Seedling Peas.

Criterion is supposed to be a cross between Advancer and Ne Plus Ultra, and was considered by the raiser to be one of the finest of the seedlings. In general appearance it partakes much of the character of the Ne Plus Ultra, while, as a second early, coming into use somewhat in advance of Champion of England, it is valuable on account of its fine quality and free cropping properties.

The plant is of a strong robust branching habit, and grows from 5 to 6 feet in height. The pods, which are produced in pairs, are of a deep olive-green shade and exceedingly well filled, generally containing from seven to nine Peas. These are of a fine deep green colour, and remain a long time fit for use. When boiled they are of a fine rich flavour, and, retaining their beautiful deep green shade of colour, have a very attractive appearance on the table.

Mr. DRAPER, *The Gardens, Seaham Hall*, says:—"Your New Pea has proved to be a first-class sort, suitable for general crop. It has six to eight Peas in a pod, of large size, and it is also a good cropper, and the pods are well filled. I exhibited it at the Seaham Horticultural Show, and got First Prize, against seven others."

Mr. JONES, *The Gardens, Bentley Priory*, says:—"I have formed a very decided and favourable opinion of your New Pea, Criterion. With me it grew about 4½ feet high, with a mass of beautiful green pods, averaging eight Peas in each, with the look and flavour of Ne Plus Ultra, and being so early I think it just the Pea wanted."

From *The Florist*:—"Messrs. Standish & Co., of Ascot, who have raised a very promising batch of New Peas, have just adopted the name of 'The Criterion' for that which has been set apart as the best of the series. It is in every way an excellent Pea. Being one of the Wrinkled Marrows it has a fine sweet flavour. It is in use a fortnight earlier than Ne Plus Ultra, and is a good bearer, with well filled pods, resembling those of Laxton's Supreme, and having thick fleshy husks. When cooked it is of grass-green colour, and, being of a delicate texture, will, it is said, keep longer in use than any other Pea, partaking, in this and in other respects, of the character of Ne Plus Ultra, which was one of its parents. We look upon the Criterion as one of the most valuable of the New Peas."

Mr. BRESE, *The Gardens, Petworth Park*, says:—"Criterion was sown under the same conditions and on the same day as British Queen and Ne Plus Ultra. I think it is a finer looking Pea than either of these, a heavier cropper and finer looking pod, and quite a week earlier. It is undoubtedly a good Pea."

Mr. McINDOE, *The Gardens, Hutton Hall*, says:—"Criterion, when boiled, has a beautiful dark green colour and a most delicious flavour. I think it cannot fail to become a great favourite where high-class deep green Marrow Peas are esteemed."

Mr. GILBERT, *The Gardens, Burghley*, says:—"Through your kindness I am enabled to give an opinion of Standish's New Pea, Criterion. My small packet was all sown in pots in one of the cool houses, planted out in April, withstood such a succession of cold, stormy, and frosty weather that I despaired of ever getting any Peas at all, nevertheless they braved it all and were ready for picking June 18. Criterion Pea grows from 5½ to 6 feet high; a Green Marrow of the most delicious flavour, bearing in pairs from sixteen to eighteen pods, with an average of eight Peas in each. It is the hardest and best Pea of the British Queen type."

Mr. SPEED, *The Gardens, Chatsworth*, remarks:—"It is the finest of all late Peas that I know, and is an excellent flavour and good colour when cooked."

Price, 5s. per Quart.

PRICE TO THE TRADE ON APPLICATION.

ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA, S.W.

PAXTON'S CALENDAR.

Now Ready, a New and thoroughly Revised Edition of the

COTTAGER'S CALENDAR OF GARDEN OPERATIONS.

ORIGINALLY COMPILED BY THE LATE SIR JOSEPH PAXTON, M.P.

OPINIONS OF THE PRESS.

"It has been carefully revised by an experienced gardener, and the lists of vegetables, fruit, and flowers have been corrected by the substitution of the most approved modern kinds, in place of those which were mentioned in the first edition, and many of which have ceased to be worthy of cultivation. It is a thoroughly sound, practical treatise; but it has been so long before the public, and so deservedly appreciated, that any special commendation of it now is unnecessary."—*Midland Counties Herald*.

"This is a handy volume, consisting of seventy pages of letterpress and illustration, containing much and varied information likely to prove useful to all cottagers, &c., who possess a garden. To all such, who require a cheap and reliable book of reference, we heartily recommend it."—*Lloyd's*.

"We are quite glad to see this useful little book once more, and it is like a whiff of perfume from the heather in bloom to read on the wrapper 'two hundred and twenty-first thousand.' We advise all who are interested in the promotion of cottage gardening to sow this little book broadcast."—*Gardener's Magazine*.

"The information conveyed in this little book is well adapted for all persons having small plots of ground. The necessary operations for each month are clearly laid down, and are of a thoroughly practical nature. The sorts of both fruit and vegetables are well selected, many of them being excellent in quality. To our readers who are interested in the cultivation of their flower and kitchen gardens, we can safely recommend this as being a most concise and useful work."—*Bell's Messenger*.

Price 3d., Post Free 3½d.

 WILLIAM IRELAND, Pilton Nurseries, Barnstaple.

-SATURDAY, NOVEMBER 24, 1877.

PLANT NAMES : THEIR PRONUNCIATION.

IN continuation of the remarks made last week, we now give some additional rules for the pronunciation of plant names.

VI. In modern times it has become the practice to bestow commemorative names, or such as will preserve the memory of distinguished men and women. These are exemplified in *Milleria*, *Boltonia*, *Richardsonia*, *Wellingtonia*, *Sutherlandia*. The number is now very large. Those in Loudon's *Encyclopædia* alone count up to over 700, and in the index to Lindley's *Vegetable Kingdom* there are hundreds more. Commemorative names, with the exception of the few that point to Pliny, Aristotle, Theophrastus, &c., and the few mythological ones, such as *Artemisia* and *Dionæa*, have no classical foundation; therefore they have to be dealt with, in part, from another point of view. The pronunciation to be given to them is that which best accords with the one employed in ordinary English converse when speaking of the men themselves, engrafting upon this what we have learned from the classical names after the fashion of which the terminations of the commemorative ones have been moulded. Euphony and common-sense here come to our aid most particularly. Ordinarily, in commemorative names, the accent falls upon the antepenult, as in *Hooke'ria*, *Mentz'elia*, *Dalton'ia*, *Veitch'ia*, *Ga'gea*, *Lightfoot'ia*. Sometimes it falls on the penult, as in *Liste'ra*, *Torrey'a*, *Dampie'ra*; also in the complimentary names applied to species, which end in *anis-a-um*, as in *Hookeria'nus*, *Harris'iana*, *Wallich'ianum*. In commemorative specific names which end in *i*, denoting discovery or first description of the plant, this letter is sounded like *eye*, as in *Fraseri*, *Roberti*, *Gibsoni*. In those of the same class which end in *ii*, the first *i* is short, and the second is again sounded like *eye*, as in *Smithii*, *Fortunii*, which are pronounced *Smith-è-eye*, *Fortun-è-eye*.

When the names of the persons commemorated belong to foreign languages, in which the sounds given to the letters are often very different from those which they bear in England, upon arrival in our own country those names of course conform to the English methods, and become, as it were, Anglicised or nationalised.

Whatever may be the Continental pronunciation of *Kölreuteria*, *Schweiggeria*, *Wachendorfia*, &c., in England they are to be pronounced as if they were English. There are persons, however, who assert that we ought to affect to be Continental when we happen to have got some notion as to how to do it. They assert that instead of saying *Dahlia* and *Fuchsia* in the way that Englishmen have decided to do, by almost universal consent, we ought to say something like *Darlyer* and *Fooksyer*. How the Swedes pronounce *Dahl* we do not know, and therefore cannot say anything about it. The peculiar sound given by a German to the base of the other, or *Fuchs*, is unknown to the English language, it cannot be illustrated by comparison with any colloquial English word, and can only be approximately represented on paper; even if it could be readily taken up by English lips, to propose to

SPECIAL ADVANTAGES OF RENDEL'S PATENT System of Glazing.

This system is now being universally adopted by Her Majesty's Government, several of the leading Railway Companies, some of the principal Corporations, including the Metropolitan Board of Works, Commissioners of Sewers, and the New Winter Garden Companies throughout the country.

There is an enormous saving in the Maintenance and Repairs of Roofs on this System—say from 80 to 90 per cent.—and there is no reason why a Roof should not be as perfect in 20 years as the first week, because all the perishable Materials, such as wood, iron or paint, are completely covered by the glass from the destructive influences of the weather.

Another great recommendation is, that there is no breakage from contraction or expansion either from heat or cold, as the glass has full play in every direction. Tens of thousands of squares are broken from this cause every year. Nor is there any breakage from vibration of large Railway Roofs in heavy gales of wind, or from the passing of express or fast trains. Indeed, it is well known that a pitched roof is never perfect in a station where express trains run through.

In adopting this system, all the everlasting expenses of repainting or reputting are completely done away with; and as it is now used by several of the Great Railway Companies, an enormous saving will be effected—it will have a considerable influence in supplying an addition to the yearly dividends.

SUMMARY OF SPECIAL ADVANTAGES.

- 1.—Saving of from 80 to 90 per cent. in maintenance and repairs.
- 2.—No breakage from contraction or expansion, from heat or frost.
- 3.—No breakage from vibration caused by heavy winds or passing trains.
- 4.—Squares of glass can be instantly replaced.
- 5.—The construction is very strong and durable.
- 6.—The glass can be put on in one-fourth the time of the old plan.
- 7.—No drip from condensation.
- 8.—Putty, cement, felt, &c., are entirely dispensed with.

WILLIAM EDGCUMBE RENDEL, 3, Westminster Chambers, Victoria St., London, S.W.

ape the Germans whenever we want to say Fuchsia, is simply to recommend people to make themselves unintelligible and ridiculous. That there is a genus called Dalea, which not one gardener in a thousand ever so much as even heard of, is no reason for superseding the accustomed sound given to Dahlia, familiar for half a century, and established throughout the length and breadth of the land. The one great object in the use of all language, botanical names included, is to speak so as to be understood, and this would be entirely negated by conceitedly saying Darlyer, &c.

Diphthongs and digraphs occurring in commemorative names have the accustomed classical sound, as in Furcraea, Alstrœmeria, Weigela, Weinmannia. The non-classical digraphs found in Braya, Heynea, Tofieldia, Sloanea, Raylea, &c., follow the English custom. In commemorative names there is also, now and then, a doubling of *e* and *o*. Here again the two reckon as a single syllable, as in Teedia, Teesdalia, Woodsia, Doodia, Charlwoodia.

VII. Besides the names inherited from the ancients, those compounded of classical words, and those of the commemorative kind, there are many which have been founded upon the native appellations of the plants, such as Skimmia, Petunia, Nelumbium, Genipa, Metaiba. The nature and origin of these very soon becomes apparent to the careful and industrious; no damage comes of first searching for them in the dictionary, and how to pronounce them is learned by comparison with similar ones of genuine classical birth, euphony and common sense acting, as before, as referees.

VIII. In words of more than three syllables, whatever their derivation, there is also a minor or subordinate accent, which falls at or near the beginning. In Anæctochilus, for instance, it falls upon the *æc*, and in Odontoglossum upon the *don*. The minor accent is subject to the same rules as the accent in chief. The ear is generally a sufficient guide to its proper place, as implied, among other things, in the opening remarks in my first paper on the general subject of plant-names, when, not without design, I spoke of "aural civilization."

IX. Whoever proposes to look out derivations, &c., in a lexicon, of course makes himself acquainted, in the first place, with the peculiarities of the Greek alphabet. Take, in the first place, the consonants.

(a.) Latinised Greek words beginning with *c* are found under *κ*—Comarum, κομῆρος.

(b.) When beginning with *ch*, they are found under *χ*, as in the initial portion of Cheiros-temon.

(c.) When beginning with *ph*, they are found with *φ*, as in the first portion of Philodendron.

(d.) When beginning with *ps*, they are similarly found under *ψ*.

(e.) And when beginning with *th*, under *θ*.

(f.) There is no separate character in Greek for *h*, the aspirate being expressed by the mark ' placed over the vowel. Hexacentris, as to its first part, is derived from *ἕξ*; Hypolepis, as to its first part, from *ὑπο*.

(g.) The same rules apply when *c*, *ch*, *ph*, *ps*, *th*, occur in the body of words derived from the Greek.

(h.) When *n* precedes *ch* or *g*, in words derived from the Greek, it represents an original *γ*, as in Catanan'che.

X. Secondly, as to the vowels. The Latin *æ* represents the Greek *αι*, as in Æthusa. The Latin *œ* represents *οι*, as in Anæctochilus. The Latin *i* is often an abbreviation of *ει*, as in Conium; and the Latin *u* of *ου*, as in Arctopus. The Latin *y* often represents the Greek *υ*, as in Lychni, λυχνος.

XI. In the Latinising of Greek words the terminations are often slightly altered—phyllum, for example, represents *φύλλον*. For the sake

of euphony, also, the concluding letter of the first member of a compound word is often omitted, as in Poly-podium from *ποδύς*.

XII. Occasionally, again for euphony's sake, the genitive is employed instead of the nominative, as in Trichomanes and Callitriche, from *θριξ*, *τριχος*; Myosotis, from *οὖς*, *ωσος*. The Linnean terms ending in *-andria*, and in *-andrus-a-um*, are formed from the peculiarly contracted genitive of *αυρς*.

XIII. Miscellaneous rules as to consonants:—

(a.) *C* and *G*, when followed by *a*, *o*, or *u*, are sounded hard, or as in cat and get, Galium, Cornus, Cupressus, Gunnera. Before *e*, *i*, and *y* they are soft, as in city and giant, Celsia, Citrus, Cyrilla, Gentiana, Gillenia, Gynierium, Gymnogramma.

(b.) The digraph *ch* is in classical names pronounced like *h*, as in Chelidonium, Cichorium, Cochlearia, Schoenus. But in commemorative names the sound usually follows that given in the colloquial, as in Charwoodia, Richardia.

(c.) In words like Pteris, Cnicus, Gnidia, Cneorum, Czackia, Gmelina, Gnaphalium, Mniium, Psamma, Psidium, Psoralea, the initial consonants being uncombinable, the first is dropped, and we say 'teris, 'nicus, 'nidia, &c.

(d.) *Ph* always has the sound of *f*, as in Phleium, Phlomis, Phlox.

(e.) *S* at the end of a word is sounded as in grass—Dactylis, Ophrys, Stachys, Serapis, &c. But when preceded by *e* or *u* it takes the sound of *z*, as in Ribes, Trichomanes, Limnanthes, Lens, Bidens.

(f.) *X* at the beginning of a word is sounded like *z*, as in Xanthium, Xyris, Xanthorrhœa.

(g.) *C* and *t* in the middle of a word, when followed by two vowels, are pronounced like *sh*, as in Vicia, Bletia, Spartium.

(h.) *S*, under similar circumstances, changes to *zh*, as Blasia.

XIV. Miscellaneous rules as to vowels:—

(a.) When a name ends in *a*, this letter is pronounced like the interjection *ah*, somewhat subdued, as in Sticta, Selloa.

(b.) When a name ends in *e*, the letter is always sounded in full, or as in Annë and Phœbë. Thus Orobanchë, Silenë, Elatinë, Æglë, viridë, arvensë, rivalë, acrë, palustrë.

(c.) So with *es* final, as Trichomanes, Calophanes, where the latter half of the word is sounded, not like that of counterpanes, but as *a-nes*.

(d.) Under Rule I. (c) it was stated that the *oi* of such names as bromoides is not a digraph, like the *oi* of dioicus-a-um. The *oicus* of the latter word represents the Greek *οικος*, a house. In bromoides the *o* has nothing to do with the *i* of the *ides*, the latter being representative of the Greek *ειδος*, resemblance. Therefore we say *ocymo-idës*, *musco-idës*, *hypno-idës*.

(e.) When in words derived from the Greek, *o* comes twice, as in Aizöon, the first *o* is sounded distinctly, as in zöology, zöophyte.

(f.) Certain Latin adjectives resemble Gladiolus and the other diminutives spoken of under Rule IV. (d); care must be taken not to confound them, as they are totally distinct, the accent here falling upon the penult, as in scario'sus-a-um, folio'sus-a-um, cilio'sus-a-um, glareo'sus-a-um. A few of these adjectives have been employed for generic names, as Scabio'sa, Glorio'sa.

(g.) The diphthongs *æ* and *œ*, and the digraphs *e i* and *o u* always take the accent when they occur in either the penult or the antepenult, as in Cratægus, Melanorrhœa, Veltheimia. They do not take it when occurring in an earlier position—not, for example, in Elæocar'pus, Æthusa, cæspitosus, cœruleus. The same rule applies to single vowels which are representative of digraphs in the original language, as in Eri'ca, Lissochi'lus, Alopecu'rus, Potamoge'ton.

(h.) Two vowels coming together do not necessarily constitute a digraph, although they may simulate one, as in Sila'us, Me'um, Rhe'um, Phle'um, Hype'cum.

I do not presume to say that the above rules and principles cover every possible case; neither do I assume not to have forgotten anything. But in default of the possession of a copy of Loudon's *Encyclopædia*—or, as regards the names of British plants, of Hooker or Babington—they will at all events serve as a finger-post towards what in England is held to be right and practically best. They are the rules according to which the above-named authors have acted in placing their accents, consciously or unconsciously, though possibly enough mistakes have sometimes been made, all men being liable to err and to forget. *Leo Grindon, Manchester.*

New Garden Plants.

MASDEVALLIA TRIGLOCHIN, n. sp.*

I knew very well that Mr. Lehmann, the zealous Orchidist, had discovered a new Masdevallia of the Triaristella group in the hunting grounds of Hall, Jameson, Wallis, Krause, Spruce, Roezl, Klaboch, Sodiro, and André, for I possess a very satisfactory set of dry specimens (not miserable scraps) in my herbarium, where the lovely genus Masdevallia is not very poorly represented. Yet I was quite overcome with astonishment when, the other day, the marvellous gem stood alive before me, in a little box sent by my oldest English Orchid correspondent, Mr. Stuart Low. There it was, adorned with its lovely charms. Yet, let me speak coolly of the new species, since all the praises I can heap on it will not be sufficient to give any idea of it to the benevolent reader.

The leaves are not much longer than 1½ inch; they are cuneate-spathulate, acute, very narrow, very thick, light glaucous green, with numerous violet spots underneath. The slender peduncle is bent, and not much longer than the leaves. It bears more than one flower ("several succedaneous flowers" Mr. Lehmann writes on the label). The upper short triangular lip of the flower ends in an erect rather thick tail. The lower lip has a conspicuous chin, is boat-shaped oblong, and bears on each side before its blunt apex a diverging tail. The tails are shorter than in Masdevallia triaristella, the gem of Messrs. Veitch; the whole of this is red, excepting the tails, which are yellow. Now we must look to the interior mystery. The petals are ligulate truncate with a medium apex, a little toothletted at the top, pallid yellow with a red blotch in the disk. The lip is ligulate obtuse, sagittate at the base, much narrower at the apex, pallid yellow, with some red on each side at the base. The green slender column is bent, with a toothletted yellowish white cucullus around the androclinium.

Both Masdevallia triaristella and tripeta, the late M. Eodres' beautiful discoveries, have much narrower leaves. Masdevallia triaristella has a much longer peduncle, and much longer tails or bristles to the perigoe. Masdevallia tripeta is more like M. trigloch, but its peduncle is much longer, its petals are sharp tridentate, and there appear to come several flowers in succession.

It was in June when Mr. Lehmann found this novelty, at an elevation of 5500 feet. All Orchidists will be very pleased to thank him for the discovery, and Mr. Low for the lucky introduction. *H. G. Rehb. f.*

BOMAREA OLIGANTHA, Baker, n. sp. †

A native of Peru, imported by Herr Leichtlin, and flowered by him at Baden-Baden in June of this present year. It belongs to the true Bomarea, with simple pedicels and sub-equal perianth-segments. Of published species it comes nearest B. Halliana,

* *Masdevallia trigloch*, n. sp.—(Triaristella.) Desce cæspitosa; foliis cuneato-spathulatis obtuse acutiusculis (microscopice bidentatis apiculo mediano prope oblitterato) crassis, pedunculo folia haud multo superante, unifloro primum, floribus paucis hysterocronis sequentibus; perigonii labio superioris triangulo in caudam subæquilongam exsertuto; labio inferiori cum mento magno abrupto naviculari obtuse acuto; cauda utriusque abbreviata divergente; tepalis ligulatis apice retuso serratis cum apiculo mediano; labello lineari pandurato postice sagittato; apice deorsum inflexo; columna trigona gracili; androclinii cucullo denticulato.—Lo Ecuador detexit opt. Lehmann, Junio, 1877. *H. G. Rehb. f.*

† *Bomarea oligantha*, Baker, n. sp.—Caulis gracilis glabro scandente; foliis membranaceis oblongis acutis facie glabris dorso pubescentibus; umbellis 1-2 floris; bracteis parvis lanceolatis; pedicellis glabris simplicibus flexuosis subpollicaribus; perianthii subpollinaris segmentis subæquilongis, exterioribus oblanceolatis minute cuspidatis cæcis rubellis intus luteis, interioribus ovato-cuneato-unguiculatis luteis distincte cuspidatis luteis maculis parvis opacis rubro-purpureis decoratis; staminibus tribus longioribus perianthio vix brevioribus antheris parvis oblongis.

Herbert, *Amaryll.*, p. 117, tab. 10, fig. 3, from which it differs by its shorter, broader leaves, pubescent on the veins beneath, and fewer flowers, with glabrous pedicels and small bracts. According to the sequence followed in Kuoth's *Synopsis* it would rank beside *B. variabilis* of Herbert.

Stems wide-climbing, slender, glabrous. Leaves with a short, winged, twisted petiole, oblong, acute, about 2 inches long, membranous in texture, with close ribs and obscure cross-bars, bright green on the upper surface, ciliated on the ribs beneath. Flowers one or two to an umbel, on simple, flexuose, glabrous pedicels, about an inch long. Bracts small, lanceolate. Periaoth regularly funnel-shaped, about an inch long above the small globose ovary; outer segments slightly shorter than the inner, oblanceolate, under $\frac{1}{2}$ inch broad, obtuse, with a minute pilose apiculus, unspotted, reddish on the outside, yellow within; inner segments obovate-cuneate, with a claw as long as the blade, broadly rounded at the tip, with

above the floating leaves, which are of an oblong shape. In addition to its beauty it has the additional charm of fragrance. The plant is a native of the Cape of Good Hope, and is seldom seen except in botanic gardens, though its beauty is such that it should surely find a place wherever a tank can be found for its reception. In two places that we know of it grows vigorously and flowers freely out-of-doors—one in the lake in the Edinburgh Botanic Garden, the other in the nursery of Mr. Parker, at Tooting. In both cases the ponds are fed by a spring, which seldom or never freezes. Mr. Parker's plants seed freely, and this has enabled him to select a fine strain, one spike of which is represented in the accompanying illustration (fig. 127). A slice across the flower-stalk will reveal a very pretty arrangement of the air-canals, by which the stalk is traversed throughout its length.

probably feels justified in going a step farther and may say, that while many new plants are put into commerce that fail to answer the high expectations formed of them, on the whole the new vegetables (which are in the main good selections) do not fail to satisfy; and this conclusion is somewhat borne out by the fact that nearly every variety of so-called new vegetables is favourably reported on by some cultivator in the columns of the gardening Press. The estimate formed of these testimonials by the gardening public is another matter.

An examination of this trial of Cabbages showed that certain types or varieties have a superiority over others for their obvious good qualities. One of the earliest and dwarfest of the Cabbages is Little Pixie; it takes up but little room and turns-in quickly, therefore it is suited to small gardens. It is like the Ox-

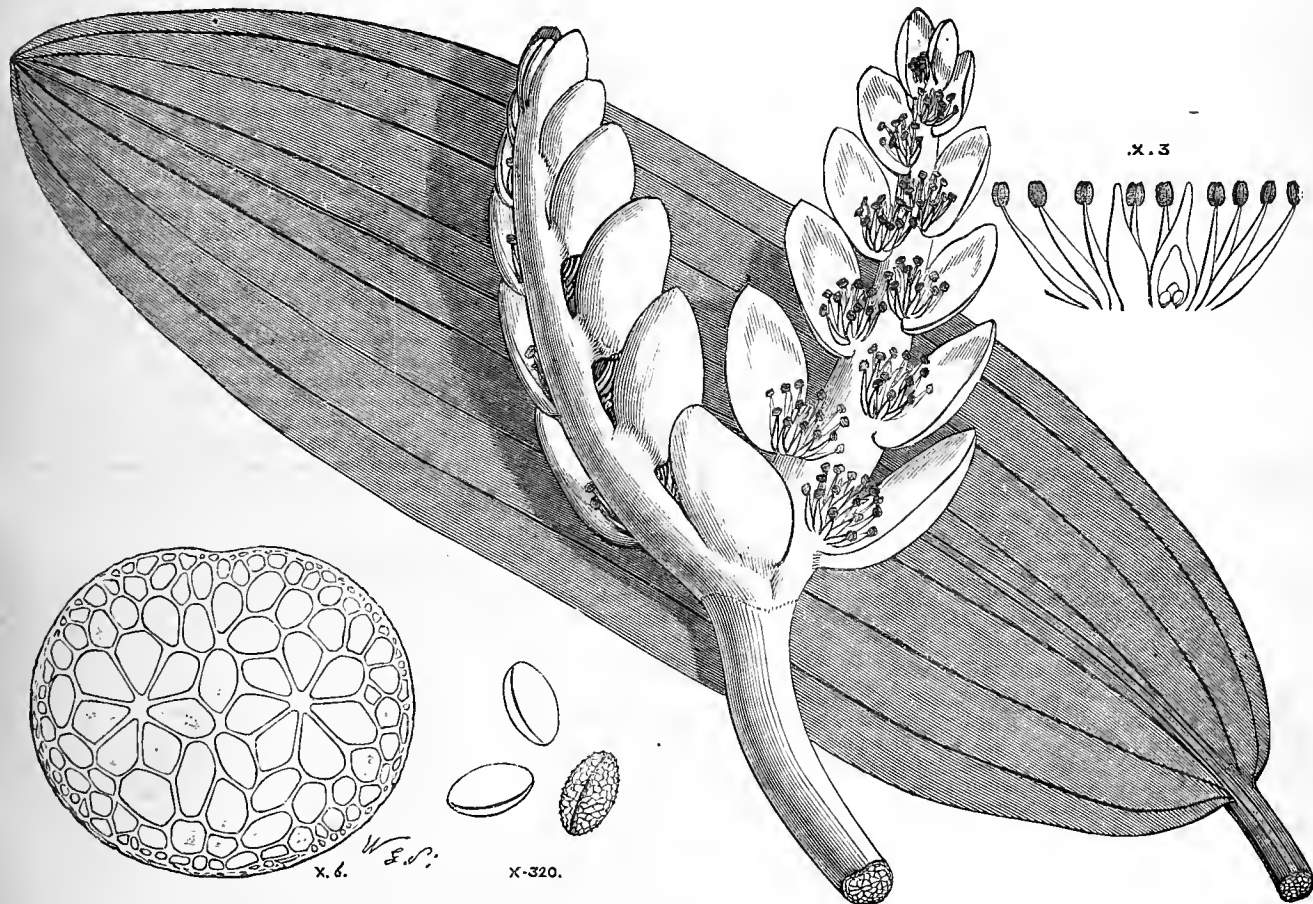

FIG. 127.—APONOGETON DISTACHYON. FLOWER AND LEAF NATURAL SIZE, POLLEN GRAINS AND SECTION OF STEM MAGNIFIED.

a distinct cusp, $\frac{1}{2}$ inch broad, bright yellow, with abundant small, claret-brown spots. Three longest filaments nearly as long as the periaoth limb; anthers oblong, $\frac{1}{2}$ inch long; filaments subulate. J. G. Baker.

APONOGETON DISTACHYON.

THIS abominable appellation for a lovely plant may be commended to Mr. Grindon as an exercise in pronunciation. Etymologically the name is as barbarous as it is in sound. Such as it is, however, it must be preserved, for there is none other, and any attempt to frame a new one in the vulgar tongue would result in failure. Our object in calling attention to so old a plant is to recommend it for cultivation (to many who do not know its merits. The flower-spike splits into two divisions, along each of which are disposed in two ranks, one on each side, the large pure white bracts in whose axils nestle the small inconspicuous flowers. The flower-spikes are thrown up well

CABBAGES AT CHISWICK.

THE Royal Horticultural Society has done good work in the way of collecting and testing all the known varieties of Cabbage. This important trial was carried out at Chiswick during the past summer by Mr. A. F. Barrow, with that care and attention which characterises all his experimental work; and the result was eminently satisfactory as an exhibition of types and varieties, satisfactory also in the sense that it enabled those interested in the trial to understand something of the number of old kinds constantly being put forward under new names, and claiming to be entirely distinct in character. The seedsman, probably, reason in this way—the new plant producers and dealers are having on the whole a pretty good time of it; there is existing something akin to a rage for new things in the way of vegetables; there are plenty of buyers of them, and if we can make a good selection there is no reason why we should not reap any beneficial trade result accruing therefrom. The seedsman

heart of the French. The Early York has long been a favourite garden variety, for it is dwarf, early, and can be grown close together. There are two types of this, the glazed and the glaucous form; the first-named being the one usually grown. The small Superfine Early York is a capital Cabbage for small gardens. Atkins' Matchless, an old garden Cabbage, is small and compact in character, forming good hearts of a deep green colour. As a matter of course, much depends on the character of the stock of a particular variety; the particular one under notice was all that could be desired.

Taking the Nonpareil as a type, it was found to have many synonyms. Wheeler's Imperial is a good form of it. Monarch is of this form, so is the Coconut, with its rounded, erect leaves; and so is Carter's Heartwell. It is a type that is much grown, because so useful in many ways. The Sprotborough is a large Nonpareil, something in the way of the Enfield Market.

The Furnel, or *fernelle* of the French, is a very

early Cabbage, very soft in the heart, but turning-in quickly in spring. It is somewhat coarse-looking, and in that respect will scarcely find favour with English gardeners; the heart is somewhat large also. The Sugar-loaf Cabbage is always known by its peculiar shape. Old gardeners used to swear by it, but its cultivation has become somewhat restricted of late. It has always borne the character of being a delicious table variety.

The Coleworts form a distinct type, what is known as the Rosette being remarkable for its flat, compact, rosette shape. This would no doubt be preferred by gardeners, but the London market gardeners prefer the old form, and grow it accordingly.

The Winningstadt is a Cabbage that does not receive the attention at the hands of gardeners which it deserves; it is of peculiar shape, with little outside leaves, a large full heart, moderately early, and having great distinctness of character. The Quintal or Mason's Drumhead Cabbage is handsome in character, with a peculiar habit of growth, with glaucous leaves somewhat arched or reflexed, and much veined with white. Worse ornamental-leaved plants have been put into circulation. The St. John's Day Drumhead has its early and late forms, and both are good; for yielding a supply from September up to Christmas it is perhaps unequalled, and, moreover, it can lay claim to excellent quality, and grows close to the ground; there is scarcely room for a snail to hide under it.

The Pomeranian Cabbage is a singularly distinct one, with a tall, upright, and peculiar Filbert-like growth and shape, and a pointed heart, and appears to be very good in every respect; there is no mistake as to the quantity of stuff in a Cabbage, for the heart is almost hard enough for a cannon-ball. What a hardy type it appears to be!

Then there is the thick-leaved Coutances, the leaves greyish-green in colour, with white veins, and the leaves also curiously frilled on the edges, so that it has a decidedly ornamental character. Some day, when the Cabbage comes to be used in winter gardens, this will be the first that gardeners will seize on for the purpose.

The Enfield Market or Fulham Cabbage is so well known, and so generally grown, that it only remains to be stated that it was at Chiswick in good form, with its expansive growth and large heart.

The Couve Tronchuda, or Portugal Cabbage, must not be passed over. By the French it is classed among the Savoy Cabbages; by some it is grouped among the Borecoles; and it is the Asparagus Cabbage of some of the seed-houses. It is a most delicious vegetable, and should always find a place in large gardens.

A selection of Cabbages for small gardens for sowing in spring for use in autumn should include Early York, Little Pixie, St. John's Day Drumhead, Improved Nonpareil, Rosette Colewort, and the Winningstadt for the latest, because of its hardy character. For sowing in autumn for spring use the best sorts are the Fulham or Enfield Market type.

If any amateur gardener wishes to have sensational Cabbages for exhibition in October and November let him grow the Pomeranian and Winningstadt. Sowing in the spring and growing them well all the summer, they would prove both a surprise and a sensation, and put Giant Puff-balls and big Gourds quite in the shade. R. D.

KILLING TEMPERATURES.

WINTER is here again, and its track will be marked by dead or damaged plants before long. Winter's cold gets blamed for more than its proper share of the annual "massacre of the innocents." And we sometimes think that winter's damp gets even more blame than is just in plant destruction. We sometimes think that plants are damaged or even destroyed by too much heat in winter. This applies more generally to amateurs, but is sometimes applicable to professionals. When frost or damp necessitates the use of fire-heat in greenhouses there is a tendency, where the heating medium is ample, to run up to high temperatures, which results in numbers of the plants being excited into a tender constitutional growth which weakens the plants, so that they are ill able to withstand the long cold nights and the scarcely brighter days of a British December. Growth made during dark nights and dull days is about the worst thing that an amateur can produce during winter, and many are very successful

in this way; 50° to 55° should never be exceeded in greenhouses in the absence of sun during the day, nor 40° to 45° at night, and, of two evils, it is better to go below these figures than above them. In all such structures a cool airiness should be aimed at, and, when fires are necessary to expel damp, advantage should be taken of bright days so that ventilation can be given to prevent an excess of temperature. Fires lighted under other conditions heighten and hasten the work of destruction.

Too high temperatures are not unknown in stoves. A forcing heat is always to be deprecated in any structure where the plants are at rest, as a majority of stove subjects are during winter. But there is a difference between rest and stagnation, and many plants that absolutely require rest, or cessation of actual growth for their well-being, will die outright in too low a temperature, and may yet be occasionally submitted to a lower temperature at times without injury than would suffice to kill if kept at such temperature for any length of time. For instance, most Pandanads will bear being subjected to a temperature below 40° repeatedly, with no injury whatever, if it is only for short periods, such as the hours before sunrise on very severe nights, if the temperature is got up as soon as possible during day to 60° or 65°. We have known them subjected to such treatment for days and even weeks in very severe winters, when there was even a difficulty to get the temperature up to 60° on some of the days, and yet no harm accrued. But for the majority of stove plants it is always safest to keep 55° in one's eye as a minimum, and from 65° upwards according to the weather; and in all cases when the night temperature goes down somewhere about 40° the heat should be got up to 65° or 70° with all speed, for it is stagnation that kills such stove subjects, and a comparatively high day temperature secures a circulation of the sap and a revivifying influence on the plants. While we have thus seen that Pandanads will stand an occasional cold bath of 40°—and we take this genus as an example, as what is true of it is also true of most tropical plants—we have known them die of cold when the temperature was carefully kept from going below 45°, but then, for the sake of the other inhabitants of the structure, the temperature was seldom above 55°, and for weeks together scarcely over 50° as a day temperature. It is stagnation rather than an occasional cold bath which kills many stove plants; and it should be borne in mind that plants which have received plenty of light and air, with a comparatively dry atmosphere, will bear checks much better than plants subjected to the opposite treatment.

In forcing-houses greater care is necessary in guarding against sudden depression of temperature, as, from the nature of forced growth, the plants are not so capable of standing extremes of temperature to the same extent as matured growth, even although the latter may be tenderer naturally.

Amateurs and young beginners often make mistakes in the management of cold frames, by keeping them far too close. Pansies, Auriculas, Cauliflowers, Lettuces, &c., cannot well have too much air in all weathers. Closeness favours growth, which is the main thing to be guarded against, as growth made during the dark days of midwinter is extremely susceptible to damp or frost. It is wonderful what an amount of frost the Pansy will stand if kept stout and dry by top and bottom ventilation day and night in all weathers. We have seen them utterly destroyed in frames where too much protection was given, when frost was almost altogether excluded by coverings, and we have seen them bear uninjured 20° of frost in a dry well ventilated frame. Pansies, and almost all plants of similar hardiness, invariably come through the winter strong, stubby, and robust when treated in this hardy way, while plants which may be kept living and growing by coddling are never so strong at planting time as others treated as we have indicated. Damp injures such things much more than frost, and so does a close warm (comparatively) atmosphere. Even Pelargoniums will stand a few degrees of frost much better than an atmosphere and a root medium somewhere near saturation point, and frost is always more destructive when things are damp than when dry. Plants will succumb to an amount of frost when damp that would not harm them when dry, and there is nothing that promotes dryness better than a constant circulation of air. Air, even when rain is falling, is seldom so near saturation point as the exhalations which rise from the ground, hence a close frame will become damp when an

open one would keep its state of dryness even in dull weather, and will part better with its moisture when the weather is bright and dry. Outdoor plants which suffer from damp during winter may receive much assistance if the surface is hoed on dry days. A loose surface dries much quicker than a hard battered one, and allows the air to penetrate into the soil better. All decaying leaves should be kept removed from such plants as Broccoli and other winter greens, as these are often the cause of decay. The leaves of trees, when allowed to accumulate on grass or by the sides of Box edges, cause these to die much more effectually than hard frost or exceedingly low temperatures. A. H. H.

THE RESOURCES OF CALIFORNIA.

I HAVE great pleasure in again forwarding you, from my friend in California, Mr. J. R. Cross, another long and descriptive letter respecting the resources of his adopted country. I place it at your service, should you feel disposed to give it a place in the pages of the *Gardeners' Chronicle*, where I have no doubt it will be read by many, as were his former letters, with very great interest.

We are very much indebted to Mr. Cross for taking so much pains in sending so full an account of how things grow and are managed in those highly favoured regions of the Far West, where evidently horticulture is being pushed forward on a gigantic scale with a view to profit, and with a zeal quite equal to the spirit of the times of that great country. Nothing shows the improvement and elevation of a country more than the demands for and the encouragement it gives to the rise and progress of its horticulture. No doubt, like many more, through some reason of hope deferred in this country, Mr. Cross found courage enough to make up his mind and hie away in search of fairer fields and pastures new, and that he succeeded in finding those pastures and pellucid streams is placed beyond doubt by his own admission, and very probably, we may add, even far beyond his own expectation. During the sunless summers of England we might be excused imagining ourselves in the position of Mr. Cross—still in the prime of life, in, to him, a new country, with so glorious and genial a climate, wandering up and down midst groves of the choicest of both fruit trees and flowers, which can only be viewed to great disadvantage in this country when grown under glass with acquired skill, and at enormous expense beside. Follow Mr. Cross through this and former letters, and note the detailed account he gives of the planting of his own garden, what he has already done, what he is doing, and what he frankly tells us he proposes to do. Consider all this, and imagine what pleasures of hope must swell in his breast as he wanders up and down in his own western paradise, observing peacefully and with amazement the quick maturation and profitable results of his own handywork and plodding perseverance.

At his age these scenes must to him be like the opening up or dawning of a new life, and it is to be hoped he will be long spared to enjoy the hopes and pleasures of his own toil, and continue to send us home from time to time such goodly accounts of his doings.

The straightforward description given by Mr. Cross of his own and other garden practice westward in California, bearing with it the impress of truth and reality on every line, compares favourably with Milton's imaginative description of the garden eastward in Eden. Who knows but some future Milton from Europe may one day visit California, and write a poetic description of the gardens, rivers, &c., of that great country. True, he might find wanting an original Adam and Eve, but, like Milton, supposing him to have equal genius, he might supply the want by drawing with equal vigour upon his imagination for the shortcoming material!

It is pleasant to find Mr. Cross, although comfortably situated in the Far West, and separated from us by a great space of both sea and land, still mindful of his earlier associations in this country, for we find him making mention of such names as Paul, Veitch, Rivers, Cranston, Wood, Keynes, Turner, &c. These contemporary horticultural celebrities, no doubt, he looks upon as so many burning and shining lights in the horticulture of this great country, and, taking us all at our own estimation of ourselves,

there are many such. *W. Miller, Combe Abbey Gardens.*

"MONTECITO, SANTA BARBARA, CALIFORNIA: July 6.—" I am sorry to say we are having a dry season generally throughout the State. The season is now too far gone for rain to be of use, except for corn; all cereals are so far advanced that rain now would be an injury to them. In this county we have had a few fractions less than 5 inches of rain, if we had been blessed with half as much more it would have been ample to have insured good hay crops. I bear and read of as many good crops of Wheat and Barley as bad ones; the reports are very variable, therefore we may conclude there will be enough for the demand. The Wheat crop in the Eastern States is said never to have been better, but with the war news prices here have advanced considerably. All through Southern California, in view of scanty pasturage, sheep farmers who hold them by thousands have slaughtered the lambs of this year, and in some instances the sheep, by one-half, merely for the tallow and pelt. A man can go into any of the butchers' shops in town and buy a carcass of splendid mutton for 1 dollar, but in a few months from now I expect it will be dear. Should we get early autumn rains (November we look for them), farming for the next two years in every branch will pay well; by the end of the year there cannot be any surplus stock of either animals or grain.

"The Santa Cruz Island, which I see as I am sitting writing, is wholly devoted to sheep raising; the proprietors of it have sacrificed 80,000 lambs this season. In many instances where hogs are raised largely, as they now are, so that farmers hold them by hundreds, sheep are killed and fed to them; some say, jokingly, they hope to take a clip of wool from the pig's back before next fall. As will be seen, there is an economy in a necessity: without the hogs the mutton must perish.

"Although my present means are tolerably limited I have been buying fruit trees pretty freely this season—Apples, Pears, Peaches, Nectarines, Plums, Figs, Walnuts, Apricots, Bananas, two varieties; Loquat, Guavas, Orange, Lemon, Lime, and Citron. Those of the Orange family I am just now engaged in planting: I have between 300 and 400 trees of two to five years' budding—these I am planting 20 feet apart, and in three years I hope to gather Oranges off the larger trees. June and July are considered the best months to plant the Orange—a period between the first and second growth. The operation of removing them from the nursery to here, a distance of three miles, is attended with some little trouble; each tree is dug around to a suitable ball as to size of plant, and whilst so standing a sack which will hold 20 lb. of grain is used, cutting it open and then wrapping it around the ball, and with needle and twine sewing tightly. One cut with the spade beneath the enclosed ball will sever the tap-root: lift aside, and proceed with the remainder in the same way; from twenty-five to thirty of these make a two-horse load. When planted and well-watered there are but few instances of even leaf-flogging perceptible. These will plant nearly 4 acres, which will form a nice feature as a beginning. I shall bud several hundreds on stocks of my own raising. The Chinese Lemon is generally used here as a stock for the Orange. I find by a discussion lately amongst the Los Angeles Orange growers, who have formed a Fruit-Growers' Association just recently, that they are about equally divided in opinion as to the practicability of growing the Orange by budding or seedling. Los Angeles as yet may be considered the home of the Orange in California; I hope to take a drive down there this summer, and see through the Orange groves of that county. One of its growers called on me during the winter, and stayed the night with us, which gave me a good opportunity for brain picking for my own benefit. I ordered several varieties of him, which I am expecting shortly. I intend working up a fine collection, as my place is admirably suited to an extensive cultivation of the whole family. I have a peculiar fondness for them, having had charge of a set of trees in tubs (slate) whilst in England. Now that I am situated in a country and climate each so enjoyable, I hope I may be permitted to carry out my pet scheme, and gather my Oranges by the barrel.

"From the fact of our getting so little rain this season I felt afraid to plant the land I had purposed for Grapes. I have raised plants that I had intended putting out—10 acres in Grapes of different kinds; feeling afraid to risk it, I only planted a few hundreds. These have done remarkably well, and I am only sorry now I did not put out the whole. Once watering at the time of planting is sufficient for them. In a work I have on the *Grape in California*, it is most strongly recommended to plant the cutting where it is to remain. This plan I will also adopt as a saving of labour. The Peach is also a favourite fruit of mine. Having brought in a collection of English and American kinds, I intend to work these on my own stocks for future planting. I find I can get all the kinds I knew in England of a very extensive grower in Massachusetts. I can have buds sent by mail

by the hundred or thousand. He deals largely with Rivers and others. He holds a collection, as per his catalogue, of more than one hundred varieties. I have twenty-five kinds, the very best of his collection. I find the Nectarine is not sought after so much as the Peach—everybody eats the Peach. I expect we shall have Briggs' Early May Peach sent from the Santa Clara Valley in a few days. Apricots are already in of the small, round yellow kinds. The Apricot is a splendid fruit here. It grows in common with all other kinds of orchard fruit trees, bearing 3 to 4 bushels. I am told there is a native variety, so that the introduced kinds may well feel at home here. Cherries have been in market some time past in several varieties. These are grown very fine—much finer than I ever saw them at home. The Strawberry, as I believe I have written you before, may be said to be in at all times. The growers who supply the San Francisco market have this spring formed a Trade Protective Association; prices would at times get so low that they were not worth gathering. I see by market reports a uniform price has been maintained since then. I have had them in bearing since Christmas. I shall increase the area of them, as I intend to grow them entirely through the lines of Orange trees. I have raised several distinct kinds from seed of the English named sorts, which I think much of, whilst I have plants proving true to name from which the seed was taken. My first acquaintance with Strawberry culture here and in the States impressed me that we had far better varieties in England, hence the idea of obtaining seed from named kinds.

"I have obtained a few fine plants of the Banana, which is grown so extensively in Florida. This I find is very distinct from the one which has been introduced here from the Sandwich Islands. The dwarf Musa Cavendishii, the Florida variety, is more hardy, and fruits earlier and much finer. These, when sufficient can be propagated to plant by the acre, will net a pretty good income alone. They are exceedingly ornamental grouped amongst flowering plants.

"Our little town of Santa Barbara has been very gay in its almost numberless flower gardens this season. The Tea and Noisette Roses—and of these we have both the old and newer varieties of recent introduction—have been truly splendid. *Maréchal Niel*, *Cloth of Gold*, *Lamarque*, *Gloire de Dijon*, *Reine du Portugal*, *Shirley Hibberd*, *Duchess of Edinburgh*, *Niphetois*, *Devoniensis*, and *Climbing Devoniensis*, *Souvenir d'un Ami*, and hosts of other names in the same sections—plants covering immense trellises or the sides of houses, growing with the luxuriance of Willows, and, as may be supposed, flowering in the same generous profusion. Nothing can vie with the Rose here, as it is always in flower; therefore I must say it is the home of the Teas. There are a few Eastern firms who make the Rose their special business, as do your Pauls, Cranston, Wood, Keynes, Turner, &c., from whom by mail we get all the new Roses up to date of 1876. Everybody grows the Rose, and the cry is for the newest and best. As a companion the *Gladiolus* is a splendid border plant, requiring no other care than first planting. Some grow entire beds of named varieties, others grow them amongst Rose bushes. The finest effect is seeing them grouped amongst *Dracenas stricta* and *australis*, 10 to 12 feet in height; also several species of Palms. Those at present most common are the following:—*Pritchardia pacifica*, *P. (or Brahea) filamentosa*, *Ptychosperma Cunninghamii*, *Chamærops excelsa*, *C. humilis*, *C. Palmetto*, *C. Fortunei*, *Corypha australis*, *Caryota urens*, *Livistona borbonica*, *Phoenix dactylifera*, *P. sylvestris*, *Jubrea spectabilis*, *Cycas revoluta*, *Kentias*, and several others whose names I have not now in mind. The above will, I think, show how rich, with floral subjects introduced, both small and large places may be made. Then again there is that most beautiful plant—probably the most imposing of the whole family of Coniferae—*Araucaria excelsa*; the other tender kinds—*A. Cookii*, *A. Bidwillii*, and *A. Cunninghamii*, are also here, doing splendidly.

"In climbing plants we have *Stephanotis floribunda*, *Bougainvillea spectabilis*, *Hoya carnea* and *H. bella*, *Tecoma jasminoides*, *Bignonia radicans*, *Masdevallia suaveolens*, *Tacsonia Van Volxemi*, *Allamanda Hendersonii*, *Clianthus Dampieri*, *Smilax*, *Clematis*, *Hardenbergia*, *Cobæa*, *Lophospermum*, *Jasminums*. That the above are seen growing and flowering out-of-doors the whole year is tolerably conclusive proof of the nature of our genial climate. A few plants are grown as dwarf bushes, namely, *Gardenia florida* and *Fortunei*, *Vincarosea* and *rosea oculata*, *Clerodendron fragrans*, *Allamanda nerifolia*, *Cytisus racemosus*, *Euphorbia splendens*, *Polygala Dalmaisiana*, *P. cordifolia*, *Veronica imperialis*, *Plumbago capensis*, *P. larpentæ*, *Cactus* in varieties, *Neriums*, *Lantanas*, *Statice Holfordii* and *S. sinuata*, *Begonias* in varieties. The above are usually set out as single specimens, to attain in some instances large dimensions. I could enumerate a long list of plants, but the few I have chosen will suffice to show any practical person what may be grown here, and afford far greater pleasure in walking amongst them than in growing them under either glass or canvas. All *Pelargoniums*—show, fancy, and zonals—do admirably, and the size to which

some attain is really immense. It is a flower not so generally appreciated as in England. The *Cyclamen persicum*, *Amaryllis*, *Eucharis*, *Tuberose* and *Neapolitan Violets*, are here beautiful.

"This dry season is bringing artesian wells, wind-power pumps, and iron piping into great requisition. This country is famed for some of the best designed pumps in the world; every conceivable idea is brought to bear to do with the least labour. I have a splendid spring of water in the mountains at the head of my place which I had designed at some future time to pipe down when more ample means permitted the thing being done in thorough order, but I am now at it rather by compulsion. The distance I have to convey it in iron pipe is 3080 yards. I am using 1½ inch and 1 inch screwed socket pipes. This will bring several hundred barrels daily, more even than I can make available at present. Eventually, when I shall have a great portion under Orange culture and the Florida Banana, I shall then require a vast amount of water at certain periods, so that the present cost will not be thrown away. When a person claims a spring, as I have done in this instance, a public record has to be made of it, and a written notice posted at the location for so many days, so that no person, by any circuitous route, can claim one drop of it. We have had great contentions this year for water rights. In an ordinary season but little notice is taken of them. We have had some fearfully destructive fires of late, running over thousands of acres of land, and from the dry nature of everything it has to burn itself out; in some instances it leaps along with such rapidity as to defy the possibility of cattle escaping. They originate usually by hunters and pleasure-seekers in the mountains. The letter of Mr. Veitch which you enclosed I read with much pleasure, and I will endeavour to get him the cones of the kinds named, and anything in seeds or bulbs I can collect I should feel a pleasure in forwarding to him. He should try and induce some of his well-to-do applicants for situations to take a trip here for a living, as California of to-day differs vastly, widely, from that of seven to ten years past. The remarks to my note which you sent to the *Gardeners' Chronicle* might have a deterrent effect on the half-nerved person in coming out here, but not on the fearless and not over-nice man, who can turn his hand generally to most kinds of work—and he is permitted to wear gloves, too, if it has been his wont. I may mention by the way the Americans perform all work possible with a gloved hand, so that no one with ordinary courage need fear the result of his venture. I hope in my next letter to give you a good account of my Orange ground, I shall go on buying and propagating the whole family, for I feel assured there is more money in them than in anything else. *J. R. Cross.*"

REV. CANON GEE ON FAMOUS TREES OF HERTFORDSHIRE.*

(Concluded from p. 536.)

THE largest tree that I know of, and seemingly the oldest in Herts, is the Spanish Chestnut tree at Little Wymondley, near Baldock. It is now the wreck of a wreck. There is not a half of its circumference standing, though a print at High Elms, of the year 1790, shows the tree as then perfect. An original girth of 42 feet is claimed for this Chestnut and possibly may have been attained, but if so the tree must have projected on the fallen side and would not be anything like a circle with what is left. It is still a grand old tree, and one is ready to believe that it was standing at the time of the Conquest. There is no mention of it, however, in the Domesday Book of the parish. Next to the old Chestnut at Wymondley, the largest girth that I know is of a pollard Oak in Moor Park, that measures 25 feet, and another near it measures 23 feet. There is also in this park a prostrate Lime mentioned in Johns' book as among the largest in England. It must have been a fine tree though, like the *Codicote* tree, its size lay in the space that it covered, rather than in its height or girth. Close behind it, and in the avenue or row skirting the park, is another Lime in full vigour, girthing 23 feet. This is a beautiful tree. There are two Beech trees in Cassiobury Park, going to the Swiss Cottage, both of which reached my standard of fame. Lord Verulam writes me word that the Kennel Oak, at Gorchamby, measures 23 feet. The Queen Oak measures 20 feet, and he has a Lime which measures 22 feet. He gives also as just below my standard (being 19 feet 10 inches) the Kess Oak, the origin of which title his lordship thinks, is that the Oak was cased or fenced. By-the-bye, do you care to know that the many Gospel Oaks in the country had their names from the fact that, in perambulating the parishes, the Gospel for Rogation Day was formerly read when the beaters of the bounds reached that particular Oak. I will state there is no tree in my list, but

* Extracts from a paper read before the Watford Natural History Society.

examples of it exist somewhere, reaching at least my unit of fame—a girth of 20 feet.

HOW TO ESTIMATE HEIGHT.

Now with regard to height, you may say, "It is all very well to measure girth, but how are you going to measure height?" Who is to tell us whether a tree is 130 feet or 140 high? I can give you two rules of thumb, which will at least assist calculation. This is one. Supposing your tall friend to stand out well in the open; set by the side of him a stick of ascertained height, say of 6 feet. Watch at the proper hour the length of shadow cast, both by your 6-foot rod and by the tree. Then calculate in proportion the height of the shadow-casters; e.g., if the tree's shadow be twelve times the length, take its height at 72 feet. Or, take three laths, join two of them at a right angle, and make each lath containing the angle to be of the same size. Then unite the equal sides with a third, subtending the angle. Now hold it level and opposite the tree. Walk away until your eye looks up the third and long side precisely to the summit of the tree. You may now consider yourself to be standing at the apex of an enlarged triangle, of which the ground line is one side and the erect tree another. You measure the ground line, and in so doing you measure the height, for it equals the perpendicular which you thus get. We then tried our triangle upon the tallest tree that I know about here—on the Spruce in the Cassiobury Woodwalks, and found the height to be some 135 feet. Timber trees are not very high, if Brown, in *The Forester*, be correct in giving the following as the mean average height of trees:—Oak, 45 feet; Ash, 38 feet; Beech, 45 feet; Birch, 47 feet; Elm, 44 feet; Lime, 44 feet; Poplar, 43 feet; Fir, 57 feet; Chestnut, 44 feet; Sycamore, 37 feet; Yew, 16 feet.

THE PANSHANGER AND GRIMSTON OAKS.

I have reserved as an example of a tall tree the Panshanger Oak, which is now, I regret to say, "in a very poor way," and not long for its present lofty position. The ground appears to be undermined beneath it. The whole height, as given me by a timber dealer's measurement, is 73 feet, but I distrust his measuring to the very top of what he would call waste. Indeed, another measurement gives twice this, 140 feet, as the extreme height, but that again has not my confidence. The branches he states stretch southwards 60 feet, and northwards 35 feet, making a shelter of some 100 feet in diameter. All accounts agree that it increased rapidly in the later years of its growth. According to Clutterbuck, between 1719 and 1805 it added 480 cubic feet of timber to its contents. A certain Mr. Barker, timber measurer, of Bishop's Stortford, says that this growth had not ceased in 1795; further, that in fifteen years from 1710 it had increased only $1\frac{1}{2}$ inch. The value of the tree, as containing seventeen loads of timber at £15 per load, with top and bark, the valuer, Mr. Ellis, in 1811, places at £225. There is another and a nearer tree, an Oak of this same character, which I wish to commend to you. It is the Grimston Oak at Oxhey. This tree, insufficiently known, stands a few yards from Oxhey Chapel, at the fence of Mr. Blackwell's farmhouse. This tree is 17 feet in circumference, 24 feet in "length," which means, I suppose, the length of its branches. I should have taken it to be about that number of feet to the branches. It is a very well-grown tree, very dear to the Gorbambury family, who, I am informed, have commended it to the care of the new proprietor of the estate. It was planted by James, second Viscount Grimston, who died in 1773, and who had married the daughter of James Askell Bucknall, Esq., the heiress of Oxhey. The tradition of the family, Lord Verulam tells me, is that his great-grandfather planted this tree with his own hands. Supposing him to have planted the tree some twenty years before his death—his eldest son was twenty-six years old at his death—you get a fair idea what a well-grown Oak would become in 120 years' time.

I would like to mention an Ash in my parish, not because of its extreme size, but because I do not happen to know a finer, and because it is a very well-grown tree. It stands at the Hyde Lane Farm, in Abbot's Langley parish, and is 12 feet round. It has a fine, clear, straight stem, appreciated only by standing directly underneath the tree. It once, I am told, had a narrow escape from the usual fate of trees, becoming the axle of a water-wheel. It then, many years ago, said the old top-sawyer, my informant, contained three loads of timber.

QUEEN ELIZABETH'S OAK.

I have now to speak of those trees which, without reference to height or girth, are famous from historical associations. Foremost among these stand out Queen Elizabeth's Oak at Hatfield. Half-way down the avenue leading from the house towards Hertford, and surrounded by a fence, and in not vigorous health, or of a very remarkable bulk, stands this tree, which I myself years ago visited with reverence and brought away a leaf (I would not have broken off a branch) to be preserved among such mementos of our history. I very nearly took off my hat to it. On the morning or afternoon of November 17, 1558, for poor Mary died between 4 and 5 A.M., Elizabeth was sitting under this tree when a deputation arrived from the Council to apprise her of her sister's demise and to offer her their homage. She fell on her knees, and exclaimed in Latin, "*Domino factum est illud, et est mirabile in oculis nostris.*" "It is the Lord's doing, and it is marvellous in our eyes." (Ps. cxviii.) And this motto she took as the stamp upon all her gold plate. It must not be supposed, however, that this formal intimation was a surprise to Elizabeth. My informant (Miss Strickland) says that Queen Mary had already sent her the Crown jewels and her dying request in behalf of her servants, and that Throckmorton, her confidential agent, had prematurely informed her of her sister's decease even before the event took place. Elizabeth, fearing some snare, had answered his news with a requirement that, if true, the black enamelled ring should be sent her which Mary was known to wear night and day. Afterwards—forty-four years later—when pressed to name her successor, she declared she would not send him such visitors as came to see her at Hatfield, numbers having for some days been passing and repassing on that "Great Northern Road." Most likely the burst of pious thankfulness was genuine, and was the expression of relief at the termination of a season of suspense, the tension of which "Twixt Axe and Crown" had been unbearable.

THE BOSCOBEL AND OTHER OAKS.

Noting the late season of the year, November 17, at which this hardy Queen had seemingly sat out-of-doors, I hope that it will not be impertinent of me to correct here a mistake of which I have certainly heard a young lady guilty with regard to another famous Oak tree. "Ah!" said an accomplished fair one to me on a chilly May morning, when the spring was very backward, "King Charles could hardly have been hidden in the Oak on the 29th of this May." No, my dear miss, nor was he hidden on the 29th of any May. The battle of Worcester, as the battle of Dunbar—Cromwell's two crowning mercies—was fought on September 3, his dying day, and said to be also his birthday until Mr. Carlyle and others produced the entry showing that he was born and christened in St. John's parish, Huntingdon, in April, 1529. The entry into London took place on Charles own birthday, May 29, and then in memory of the Boscobel transaction the Oak leaves were worn. Of this Boscobel tree, let me say (before I leave the subject) a descendant is said to exist in Gadehridge Park, Sir A. Cooper's; but my inquiries after the truth of the tradition have been unsuccessful.

I have not quite done with Queen Elizabeth and her connection with Herts and Herts trees. There is another domain in Herts or its borders, only less closely connected with this royal lady than at Hatfield. Look into the index to Miss Strickland's *Biographies*, and you will find some half-dozen references to Ashridge. I have heard that the house at Ashridge stands partly in one county and partly in another. The parish church, Little Gaddesden, where the Bridgewater family lie buried, is in Herts. Of the Ashes which gave name to that ridge only one remains, as far as I could observe on my visit the other day. Under this tree, or one of its fellows, we may think the Princess Elizabeth also sat, and so very likely used to sit the "bons hommes" of Ashridge—the hermit priests who formerly owned that beautiful spot, and who lie in the church which the house itself includes. It will be next in chronological order to notice the Oak Wood in Gorbambury. This is a wood at the back of the house specially so called. When Lord Chancellor Bacon was in financial difficulties, it was suggested to him that he should cut down this particular wood. "What I man," said he, "would you have me pluck out my own feathers?"

And so the trees escaped, and some, I believe, are now standing. The circumstance is told in most Lives of Lord Bacon, as if it applied to Oaks generally, and they are spelt with a little "o." Lord Verulam informs me that the tale hangs round the particular Oak Wood, as distinct from another, Brook Wood, &c. I come to Moor Park to notice two traditions with regard to trees there. Moor Park was owned once by Cardinal Wolsey, perhaps in virtue of his connection with St. Alban's as Abbot *in commendam*. There is a tree which, Lord Ebury tells me, goes still by the name of the Cardinal's Oak. He described to me its exact situation. Lord Ebury thinks that it had its name rather from the fact of the Cardinal's having sat under it than having planted it. It is too old, according to Dryden's lives, to have had its beginning only some 350 years ago. The other Moor Park tradition is as to the beheading of certain trees there. The estate undoubtedly belonged to the Duchesses of Buccleuch, who is introduced into Scott's *Lay of the Last Minstrel* (canto i., introduction). This was Anne, Duchess of Buccleuch and Monmouth, representative of the ancient Lords of Buccleuch, and widow of James, Duke of Monmouth, who was beheaded in 1685. Of her Sir Walter says:—

"She had known adversity,
Though born in such a high degree;
In pride of power, in beauty's bloom,
Had wept o'er Monmouth's bloody tomb."

And, says the tradition, on her husband's execution, she beheaded sundry of the forest Oaks in the Park. This may have been done from morbid sentimentality, or from a wish to save them, as some supposed, from confiscation; or rather, perhaps, from a somewhat spiteful wish to prevent their ever being used as timber in that navy of which her husband's cruel uncle, James II., was so proud. Whatever the motive, which could scarcely be excusable, much less praiseworthy, the tradition holds good as to fact. And I understood Lord Ebury to say that it was with reference to this special legend that Froude, the historian, encouraged him to believe that wherever tradition is clear and strongly rooted, and consistent with common-sense, there is truth in the main fact asserted. I think, therefore, we may continue to believe that these Moor Park pollards had the historical origin attributed to them. There is another kind of tradition which has made some trees famous, or at least notorious. It respects those trees which grow up out of tombstones or from the crevices of vaults. Certainly some trees do seem to choose such spots. I imagine that a seed having found its way there and expanded in peace, was at first encouraged from the sentiment that it was pretty, and afterwards that it afforded a pleasant canopy to the tomb. Not until too late was it found that the intruder was master of the situation. With relentless force it crushed the monument into which it had intruded, and had altogether taken possession of the memorial. Just such an intruding Sycamore stands in Aldenham churchyard, and has made small account of stone slabs and of iron railings. But one, better known, is in Tewin churchyard, in the tomb of Lady Anne Grimstone. Our forefathers, who scarcely seem to have been wiser than ourselves, fitted on a startling legend to this tree. It is that Lady Anne was in lifetime an unbeliever, and that she arranged with some survivors (as sceptical as herself) that if there were another world a tree should grow out of her vault to announce the fact. She certainly conformed to the requirements of religion, and lived in all such ordinances blameless. Clearly she went to her parish church, and in her carefully kept account books we find that she put up her horses, as do her successors, at Gorbambury; only 200 years ago she seems to have done it somewhat more cheaply, e.g., "March, 1602, for setting up on Sunday (twice), 8*d.*; for setting up the horses at church (Fryday), 6*d.* April 15, setting up the horses when Dr. Bell preached, 4*d.*; setting up the horses when my lady stay'd (for H. C.?) at Whiteball, 1*s.* July, 1680, setting up the coach horses and black nagg, morning and afternoon, at Michaelmas, on Sunday, 1*s.* 8*d.*;" and so on. It is rather hard, after a life of such regular profession as this, to be accounted an unbeliever 200 years subsequently to one's own time, upon account of the capricious growth of a tree. It is not every one whose friends could produce so much post-mortem evidence of having lived, at least, as well as other people.

I would try to enlist on your parts a feeling of conservative preference for the older kinds of trees.

I think that our old English trees have got such a character of their own, and give such a character to the landscape, that there is a loss when their monopoly of the fields is largely invaded. I grudge to see some of the foreigners prominently introduced into what I venture to call "our parks." I know a park a few miles hence where the *Araucaria imbricata* is pushing its hard puzzle-monkey branches into the air. *Deodaras*, *Wellingtonias* (or as they are now called *Sequoias*) are following up the invasion; and I can imagine these colonial gentry will look down upon Oaks and Elms in the days of our grandchildren. I am aware that this objection is narrow, and a like narrow-mindedness, 200 years ago, would have kept out Cedars. Happily a passing expression of complaint has little effect either way. I would only press my structure so far as to urge that large planters shall not introduce these strangers in too large a proportion, and so alter the character of the English forest scenery. On a very small scale I try to keep this in mind in planting our churchyard, though I must confess to two *Sequoias* which are already becoming too large for us. I like to think of God's Acre in England as being English, and not New Zealand or Californian ground.

The one remaining reflection which I would ask to be permitted to make is as to the moral impression, or even a religious effect upon us, produced by consider-

that the duration of man takes place somewhere else. If 1000 years be the continuance in the Maker's eyes of vegetable life, then the highest form of the higher, or the animal life, cannot be on an average one-twentieth of that term. There must be, as the Psalm says, "a planting in the house of the Lord of those who shall flourish for ever in the courts of our God."

I check myself in an honest tendency to improve the occasion in the direction of my own special vocation. I will end with a verse from him from whom you would scarcely expect a very high aspiration of immortality, and yet it says all I want to say. It is said that Lord Byron wrote the following epitaph for a tomb in Harrow Churchyard. The allusion will explain itself—

"Under these green trees pointing to the skies,
The planter of them, Isaac Green tree, lies.
The time will come when these green trees shall fall,
And Isaac Green tree rise above them all."

ÆSCULUS PARVIFLORA.

At this planting season it is well to remind those who are engaged in such operations of the wealth of beauty that is at their disposal. It is vexatious to know that the nurseries abound with fine ornamental trees and shrubs which are seldom or never asked for.

FIG. 128.—B, QUEEN ELIZABETH'S OAK AT HATFIELD; A AND C, OAKS PLANTED BY THE QUEEN AND PRINCE CONSORT.

ing the longevity and slow growth, and firm hold of the earth taken by these sons of the soil. It must strike us that there is here a singular contrast to the tree-planter's own limited continuance on this same scene. A man plants an Oak, he never hopes to sit under it. When his threescore and ten years shall be run out the tree will be not half way towards maturity. The most he can hope for is, as in the case of the Oxhey Oak, that his great-grandson, though not the possessor of the tree, may keep up the remembrance of this good work. I myself have a weak hope that some Vicar of Abbot's Langley (next but three, say, after me) may speak of my Lime avenue in our churchyard as they speak at Welwyn of the Limes planted by the writer of the *Night Thoughts*, and say of mine, "These were planted in old Mr. Gee's time," but the trees themselves everywhere to be noteworthy are so old that we must rather say that in our time and turn, we belong to them than that they belong to us. How many generations of old and young have told their tale of joy and sorrow under a kiss-Oak of 20 feet circumference. How must the old tree smile to see a new generation coming to it with the old, old story. I am myself inclined to think of such a tree as the old monk thought of Leonardo's great fresco in the refectory, opposite to which so many generations came, and ate and drank, and went away, and came no more. "Surely," said he, "the figures on the wall are the realities, we in the hall are the shadows." But no: surely this suggests a notion, or encourages and strengthens a belief,

As in other matters, planters get into a groove, and so we find common Limes, Planes, Poplars, Oaks over and over again where other and better things would answer just as well. We are not derogating at all from the qualities of the trees we have mentioned, we are simply pleading for the use in suitable situations of some of the many very beautiful trees and shrubs which are so unaccountably neglected. We have from time to time given illustrations or references to some among them, and now lay before our readers another example of a very beautiful flowering tree, whose merits are not nearly so widely known as they should be.

ÆSCULUS PARVIFLORA (better known by its synonym of *PAVIA MACROSTACHYA*) is a North American tree, of medium size, with leaves similar to those of the Horse Chestnut, but not so broad near the top, and more or less downy beneath. The inflorescence consists of a mass of flowers disposed in long elegant panicles, which make their appearance in July (fig. 129, p. 657). The petals are pure white, while the long thread-like stamens are of a chocolate-brown colour. The habit of the tree is pyramidal, and it forms an abundance of suckers or side-shoots round the base of the old stem, and by means of which it is readily propagated. The effect produced by the tree when in full bloom is singularly beautiful. Our illustration is from a specimen forwarded from Valentines, where there is a fine collection of deciduous trees, by Mr. W. Earley. Among other Horse Chestnuts we may allude to—

ÆSCULUS (*PAVIA*) FLAVA, a tree generally attaining to a height of about 15 feet. It is known in America as the "Ohio Buck-eye," or "Yellow Horse Chestnut." It has downy pale green leaves and yellow flowers of such shape that it would require no very great stretch of fancy to call this the Tree Hedychium!

ÆSCULUS (*PAVIA*) RUBRA is another fine tree, native to the woods in Virginia and North Carolina. It is smaller and more slender generally than the former, and is called "the small Buck-eye." Its blooms are brownish-red in colour.

PAVIA DISCOLOR is a tree which averages 4 to 5 feet in height, the blooms being red and yellow tinted.

PAVIA PENDULA and PAVIA AZUAL are also notified as being "in the country," but we do not know them. There are also four or five superb hybrids in the hands of American nurserymen well worthy of introduction, notably *Pavia rubra* Whitleyii, possessing splendid foliage and brilliant red flowers.

They succeed planted in mixed shrubberies. Though grown as moderate-sized "clumps," separately and upon lawns, they afford a feature, when in bloom, quite unique and desirable even if we admit the drawback associated with their deciduous character. A plant of *Thuja Lobbii* for centre with a band of these around, not too near, though the *Thuja* requires little bottom room (even though it rivals the *Sequoia* (*Wellingtonia*) in height), would neutralise this in winter, and prove very effective during the whole of spring and summer, for the young shoots of *Pavias* are purple tinted in spring.

The Horse Chestnut itself, whose native country is only surmised, is a noble tree, familiar to every one, but there are many varieties of it in the nurseries which, if they do not rival the type form in massive beauty yet afford variety and interest. These variations affect principally the foliage, which presents all sorts of vagaries in these varieties. In no plant, indeed, is there more individual character shown, one Horse Chestnut will be systematically and regularly in leaf three or four weeks before its fellows, another will throw one branch, perhaps, on which the buds burst into life a week or two before those on other branches.

The double Horse Chestnut offers an advantage in that it has no spiny capsules to tempt stone-throwing boys, though it is possible the boys would look on the tree with about the same feeling as those did that Leech depicted lamenting the facts that spikes had been placed in all the posts.

ÆSCULUS RUBICUNDA has been known to sport like the purple *Laburnum*, and to bear spikes of pale yellow flowers, smaller in size and similar in colour to *Æsculus flava* (*Gardeners' Chronicle*, 1851, p. 407).

The Villa Garden.

CHRYSANTHEMUMS.—Villa gardeners by the legion grow the *Chrysanthemum* for its beauty and usefulness in autumn and winter, and some grow it specially for show purposes. Whatever may be said in disparagement of "specialists," as the cultivators of certain pet flowers are termed, it is quite certain they are on the increase, and many Villa gardeners go on from growing to exhibiting the *Chrysanthemum*, for are not suburban and local shows springing up on every hand?

As a hardy flower the *Chrysanthemum* stands alone, for it comes in at a season of the year when decay spreads on every hand, and our gardens take on that mournful appearance natural to autumn, and when there is no other flower of a similar character to gild our gardens with pleasant hues. It sometimes happens that a frost comes and destroys the rich promise of bloom, but it is of infrequent occurrence; while it is not difficult in the case of outdoor plants in certain situations to set up some screen or covering that shall hold the flower safe from harm.

OUTDOOR PLANTING: WHERE TO PLANT.—In planting *Chrysanthemums*, let them be placed against a dwelling-house, the garden wall, or any out-house, provided it be in a warm sunny spot. It is of little use to plant *Chrysanthemums* on a north border, where it is cold and sunless, more especially if the soil be cold and late. If *Chrysanthemums* be planted in the open border, early flowering sorts should be selected for the purpose; and as these are well known to nurserymen, there is no difficulty in obtaining them. How often one sees the red-flowered Pompon variety Bob planted in the open border, and it is selected probably on account of its chestnut-red colour, but it is one of the latest to come into bloom.

A few early blooming varieties suitable for planting

in the open border will be found in the following selection of the large flowering type:—*Album Formosum*, *Cassandra*, *Cassy*, *Formosum luteum*, *Gloria Mundi*, *Guernsey Nugget*, *Julia Lagravère*, *Mr. Geo. Glenny*, *Mrs. G. Rundle*, *Mrs. Sharpe*, *Orange Perfection*, *Princess Mary*, and *White Christine*. Of Pompon varieties—*Berrol*, *Cedo Nulli*, *La Sultana*, *La Vogue*, *Mdme. Eugène Dommage*, *Mdlle. Marthe*, *Rose Trevenna*, *Salomon*, *White Trevenna*, and all the varieties of *Cedo Nulli*.

If the plants can be put against a south wall, the choice varieties may be used: and there is this further advantage about a wall, that a screen can be formed of some kind to protect the plants from frost during October and November. A temporary wooden roof may be constructed with a few upright supports in front, and on the top of this roof a canvas covering may be stretched. This canvas roof should not be put over the plants before they come into flower unless actually required; for the cultivator must not expect them to make much headway under canvas. Glass is to be preferred as a temporary roofing, but it is expensive, cumbersome, and very likely to get out of order. The canvas roofing has its disadvantages also, for during the late gale a friend of ours had his screen blown clean away, in consequence of a sweeping gust of wind getting under it, and lifting it into the air. After the plants are well in bloom the canvas covering may be allowed to remain on, to keep the flowers from being spoilt by the rain, but taking care that air and light is abundantly ministered in favourable weather. A slight wooden trellis is the best thing to have against the wall to fasten the plants to by tying them; this is far better than nailing them against a wall.

HOW TO PLANT AGAINST THE WALL.—Let it never be forgotten that the *Chrysanthemum* is not only a strong growing but a moisture loving plant, and when it is planted out against a warm wall, it should be so done as that plenty of water can be administered during dry weather. In the first place the ground should be deeply dug and well manured, putting in a good layer of manure at the depth of 2 feet. Secondly, the plants should be put in a celery trench, after the fashion of Celery, and this trench should be at least 9 inches in depth. The advantage of this is obvious; in fact the main advantages flow from it, water and liquid manure can be administered by means of the trench, and a good mulching of manure about the roots can be given during the summer, and that too without exposing it too much to the drying influence of the weather. The best plants to put out against a wall are cuttings struck in March and then grown on in pots in heat if possible, stopped as required, and finally planted out in May, when sufficiently hardened off after a period of probation in a cold frame. Fine bushy plants can be formed in this manner; a good foundation is laid, and a strong quick bushy growth follows, producing well-matured wood, carrying many flowers.

PLANTS IN POTS FOR THE GREENHOUSE.—These should be struck and grown on in pots similarly with those recommended for walls, but instead of repotting in larger pots in May, we would recommend that they be planted out in a trench in rich soil, mulched with manure, and well watered when requisite. About the middle of August they can be lifted with good balls of soil about the fibrous roots, and potted into 10-inch pots, and then plunged to the rims of the pots in coal-ashes, cocoa-nut fibre, or Hops, till they begin to show signs of expanding the buds; then they should be taken to the conservatory, and watered twice or thrice a week with cow-dung manure in a liquid form. This is one of the safest and most nourishing of liquid manures. While the plants are plunged the branches should be tied out into shape, and the leading shoots stopped as required. By pinching some back a little harder than the others, and especially by cultivating early and late varieties both, a good succession of bloom can be had.

The main reason why we recommend the custom of planting out in trenches in summer is, that many Villa gardeners are called from home during the day by the claims of business, and if the plants become dry for want of water a serious check is given to them, and they lose their leaves. By planting out as recommended this danger is to a great extent averted, and scarcely a perceptible check is received by the plants at the time of potting if they receive proper attention.

PRUNING (continued from p. 526).—With a belief in Mr. Cree's theory, short experience and limited practice, no wonder that many have erred and gone astray in regard to pruning, especially in the case of Conifers. And what has been charged against Pontey as the ruiner of English woods, may be charged against Cree as regards ruining the Scotch; but with this difference, that the former was done upon a more extensive scale than the latter.

Having had frequent opportunities of witnessing the injurious results of Mr. Cree's system of pruning *Coniferae*, it may be well to describe what some of them have been, after a trial of over forty years. It may be repeated that his practice was to cut off one-half the length of all the branches from top to bottom of the tree, which, as he informs us, made their (the branch) growth afterwards much slower than before, and kept the branches in all future time slow of growth. In this the theory, practice, and results quite agree, for the branches, after being cut, cease to grow to any appreciable extent, for several years at least, and seldom ever again resume their natural or former vigour. This being the case with the branches, how is it with the stem and roots? How are they affected by the retarded and impeded growth of the branches? It need scarcely be explained that just in proportion as the growth of the branches is retarded or interrupted, so is the growth and development of the stem interrupted, though the time required for taking effect may differ considerably, owing to various circumstances, some of which are very remote, but not the less certain.

It is found on dissecting, or cutting up, any trees severely pruned, or pruned to such an extent as to produce visible effects, that such effects are all against and not in favour of pruning.

So visible is this, that on minutely examining a section of a tree severely pruned it can be correctly ascertained in what year the pruning took place; and one feature observable is, that the layers or zones are rarely so much affected the first as the second and subsequent years, showing that the injurious effects are not all at once fully experienced, but by slow degrees, modified no doubt by climate, shelter, condition of soil, and other circumstances. The object aimed at by reducing the quantity of branches, Mr. Cree informs us, is to lessen the superficies which the sap has otherwise to cover in the structure of the stem. It appears scarcely necessary to state, much less to prove, that this theory is quite baseless and false, from the well-known fact that the branches are the chief laboratories or manufactories of the sap; hence, if the laboratory be in any way injured or destroyed, that which it produces is correspondingly influenced in an unfavourable way; if the branches which perform such an important part as that of elaborating the sap are either cut off or mutilated, both the quantity and quality of the sap are thereby deteriorated, and the whole economy of the tree suffers. Pruning, therefore, cannot in a direct way increase and improve the growth of a tree. Branches not only assist in elaborating the sap, but are the principal means of conveying it in the form of cambium to every part of the tree, in a manner somewhat corresponding to that of the arteries in the animal conveying the blood to all parts of the body. The branches evidently also act in a mechanical as well as a chemical way in benefiting the tree by their influence in attracting or pumping the sap into their extremities and leaves through their motion by the winds and other elements, and the building up of the tree is in exact proportion to the health, quantity, and condition of the branches and foliage.

In regard to pruning, as a specific for diseased and unhealthy trees, by imparting vitality to them through enriching the dry unhealthy inner bark, this is only another imaginary benefit void of practical truth, suggested in all likelihood by the flush of spray, or young shoots, which bursts forth from any suddenly exposed part of them on interruption or derangement of the sap-vessels. It is quite a common thing to see trees at all stages of growth, from the sapling upwards, make a spasmodic effort to produce shoots and foliage apparently good and healthy the first season, but the next, sickness and decay in every part—the fine healthy-looking spray and leaves,

indeed, being only the product of a weak constitution stimulated by pruning, and Nature's last effort to prolong life at a dangerous and often deadly sacrifice.

Without further encroachment upon your space, and yet to preserve the thread of the subject, I close for the present, with a view of concluding in my next paper. *C. Y. Michie, Cullen House, Cullen, N.B.*

Natural History.

STORKS.—The figure of a stork's pole at p. 594, vol. vii, as seen in bulb gardens in Holland, recalled some little incidents of a stork I had some years back. Naturalists know that some kinds of birds and insects sustain death while in danger—even the stork does this. A remarkable instance of this freak was played by my bird, which strayed into the farmyard and caused much hubbub among the hens. Even the boys stared at so "comical a fowl," and gave chase, and poor stork tumbled down the sand-pit. Hearing what had happened I taxed the boys with having stoned him, but it was "No, no." Yet there lay my pet lifeless, except a slight movement of his eyes. This led me to think he was only shamming, and I told the boy to take care how he handled him. After a shake he bawled out, "He's dead's a herring," and threw storky out, but he soon gathered up his long legs and scampered off homewards. My stork, though tame, was not a docile pet when hungry—less so than the heron, seldom taking notice of one except when hungry, then becoming clamorous, and gobbling up rats, mice, and any sort of carrion or garbage. Being gorged with food he used to stand on one foot moping and lifeless, somewhat like a heron on the bank of a river watching his fishy prey. In fact, the habits of both birds are similar, and so is their great power of swallowing food; even common-sized rats, after being well swaged in water, are soon gulped down their long-extended throats. A friend told me that during a most severe frost he shot a heron, and found a snipe in its stomach! Perhaps both were on a hungry errand amongst broken ice, and the weaker fell a prey to the stronger, yet in less severe weather the heron would have preferred an eel or a rat before a snipe. *J. Wighton, Cossey Park.*

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Heaths, —Where a sufficient number are provided of autumn and winter flowering Heaths, these assist materially in keeping up the display in greenhouses and conservatories. I make use of the term "provided" advisedly, as they are seldom grown up from the cutting-pots in private establishments, and in most cases it is better that it should be so, for the especial treatment and attention they require to grow them well up to the ordinary size they arrive at before suitable for decorative purposes can, even from an economic point of view, be best left to those who cultivate them for sale by the thousand or tens of thousands, as do a few growers who make a speciality of them. It frequently seems strange to me that they are not in more general demand, for at the present day they are evidently not so much used as at one time, as even if consigned to the rubbish-heap after flowering they are still, considering the length of time they last in bloom, the space they fill, and the effect they produce, no more costly than Hyacinths; and although it may be said, and no doubt justly, that the treatment they have received to bring them up to the high condition they are in when sold out from the most successful growers, has been more of a character to give them an effective appearance for the time being than conducive to their future well-being, still if the best and lightest situations in a conservatory or greenhouse are chosen for them during the winter, and their treatment as to air, temperature, and water, is such as to show that those in charge of them do not forget that they belong to a family that will not bear keeping too close in dark situations or to be carelessly supplied with moisture, a considerable portion can be made to do duty in years to come. Heaths, generally, whether grown in large or small quantities, require particular attention at this season when the weather, as it has been all on, is moist and mild. If there was any trace of mildew on them at the time they were taken in, and this was not detected, it will spread apace: it is necessary to impress this upon young hands in their cultivation as a few weeks' inattention frequently will cause the destruction of a considerable portion of the foliage of an otherwise healthy plant so far as to make it impossible by any subsequent treatment to rectify the mischief: when a plant is ever so little affected apply sulphur at

once—at this time of the year it may be allowed to remain on for a week or two. I do not approve of the slight indiscriminate application of sulphur over the whole collection, as is sometimes done, with the intention of preventing the attacks of mildew, as when so used it often reaches the surface of the soil, from whence when water is given it gets washed down to the roots, where its effects are most injurious. Keep them both day and night as cool, by the admission of plenty of air, as can be done without danger of actual frost reaching them; give water the first thing in the morning so as to allow time for any spilt about to dry up; be careful in applying it not to wet the foliage, and also see that there is no moisture reaches the heads of the plants through drip. Wherever heat is turned on to dry up and expel moisture, let this be done early in the morning, so as to admit of its being taken off sufficiently soon for the pipes to get quite cold before night.

The softer wooded kinds, as likewise the earliest of the spring-flowering sorts amongst the harder wooded section, naturally make a little more progress through the winter than the later summer blooming, hardest wooded kinds, consequently the soil with the former should not be kept quite so dry as in the case of the latter. The size of pot proportionate with the size of the individual plant that occupies it should always be taken into account. Healthy, free-growing specimens that are somewhat under-done for root-room suffer to a much greater extent if allowed to get over dry than when the roots occupy a large body of soil. Inattention to these and similar matters of detail often produces failure, to which frequently may be attributed the abandoning the cultivation of these most distinct and useful decorative plants.

All hardy shrubs required for forcing should be taken up and potted. Where conservatories have to be kept gay, and there is an insufficiency of hard-wooded pot plants, these may be employed with advantage, as also where halls, corridors, and staircases are required to be furnished, as the hardy plants in question, being of less value, it is of less consequence should they be placed in positions not suited to their well-being. Rhododendrons have not generally set their buds well this year, consequently there may be a short supply of those miniature examples profusely studded with flower-buds so useful for pots. Their place may be supplied by *Adromedea*, *Kalmia latifolia*, *Viburnum Opulus*, *Ghent Azalea*, and the fine mollis varieties. The latter are amongst the most beautiful subjects of comparatively recent introduction, not nearly so much known or grown as pot plants for this kind of winter work as they ultimately will be. They appear to be extremely free flowerers, little plants not more than 10 inches or a foot high being thickly set with buds. Lilacs are amongst the best plants that can be used for this purpose. I should recommend all that will be required of such things to be potted immediately and placed where they can be protected from frost or too much wet.

SOFT-WOODED PLANTS.—Tree Carnations and Pinks not required for immediate forcing should be kept in frames perfectly free from drip, on a bed of ashes to exclude worms, the soil not too wet, but moist enough to keep the roots slightly moving, with mats at hand to protect from frost. A sufficient quantity of *Spiraea (Astilbe) barbata* should at once be potted, to furnish a supply through the winter and spring. Where imported roots are used, it is much better to get them into pots immediately than to heel them in as is sometimes done, merely potting as required. The same applies to *Dielstra spectabilis*, the pink and white varieties of which are amongst the best hardy plants that can be forced, provided the flowering is not hurried by the application of too much heat. *Polygonatum (Solomon's Seal)* should with the last-named be used in quantity where cut flowers to any extent are required. This, and the *Dielstra*, are two of the most effective flowers in existence, when artistically arranged, for the filling of large stands; to their elegant drooping habit must be added their lasting properties when cut. Everything of this character should be placed in pots no larger than absolutely necessary to admit their roots without unduly cramping. Give a slight watering after potting, but by no means make the soil too wet; after which plunge the pots in cold frames. *T. Baines.*

FRUIT HOUSES.

ORCHARD-HOUSE.—The final arrangement of all pot fruit trees should now be completed without delay. If potting and top-dressing are still in arrears a single day should not be lost, as successful culture depends in a great measure upon the treatment the trees receive from the fall of the leaf until they are started into growth. Formerly, when the management of orchard-house trees was not so well understood as it is at the present time, many growers used to pack them close together under glass, keeping them quite dry through the winter, and, as a matter of course, the Peaches, Nectarines, and Apricots cast a large percentage of

the most prominent and best buds on the first application of water to the roots in the early spring, whereas had they been well soaked with water prior to covering up and liberally ventilated, all these fine buds would have swelled into perfect blossoms. In some places it is the custom to clear the orchard-house of all pot trees except Figs to make room for Chrysanthemums, Cauliflowers, and other subjects requiring protection from autumn frost, and providing the wood is properly ripened I incline to the opinion that the trees are benefited by full exposure from the end of October until the beginning of January, when they should be taken back to their summer quarters. A properly potted tree is always well drained, and the soil, a free calcareous loam, is so firmly rammed as to preclude the possibility of its holding a superabundance of water through the resting period. The site for the trees should be high, dry, and open, with a good layer of ashes under and plenty of bracken or long litter round and over the tops of the pots for keeping out worms and protection from frost. Although the trees may appear quite clean when they are taken out of the house, every shoot should be carefully washed with soap and water, and all the stems and old wood painted with the composition in favour with the grower. Pruning may be deferred until the buds begin to swell, as Peaches and Nectarines which have been some years in pots make but few wood-buds; hence the shortening of a shoot, by the removal of the terminal bud, is often attended with the loss of all the bloom-buds down to the base. To obviate this it will be better for the amateur to defer pruning until the trees are taken into the house; but in well-managed trees autumn pruning is a very light affair, as summer disbudding and stopping should reduce the necessity for the use of the knife to the removal of old bearing shoots, which may be taken out as soon as the fruit is gathered. The Noblesse section, indeed nearly all the large-flowered Peaches, are not so well furnished with wood-buds as the small-flowered kinds, and on this account some gardeners are of opinion that they are not so well adapted for forcing; but with us two of the very best Peaches, *Early Grosse Mignonne* and *Abec*, from which we commence gathering in May, belong to the large-flowered sections. These we thin out, tie in full length, and shorten back when the blossoms show colour. Where indifferent or exhausted kinds have not been replaced no time should be lost in making the selection, as the demand this season is very great, and first-comers generally obtain the best trees. The choice of varieties requires great care, as many of the kinds which now swell the nurserymen's lists have little more than new names to recommend them. *W. Coleman.*

PINES.—The general appearance and character of the growth in these plants at this period proves conclusively that the climatal conditions have been during the autumnal months of such a nature as to be eminently suitable to the requirements of this particular section of plants. This is a fact which is worthy of notice, and the conditions in being at the time referred to, should therefore as far as practicable be assimilated whenever required. At the present time, however, with three consecutive months of inevitable murky and sunless weather in prospect, growth in successional plants and other young stock should not further be prolonged, but be reduced to a minimum state, and such conditions be maintained in the houses which contain these plants as will tend to consolidate the growth which has already been made. The temperature about such plants should be lowered to about 53° as a mean at night, and 55° where suckers are placed to be wintered for restarting again next spring; in both cases 65° during daylight will amply suffice, and above this point, if a little air is admitted even for an hour or two occasionally, it will be productive of much good. If these plants are placed in close compact structures, which are covered at night, but little fire-heat will be required to sustain the degrees as indicated, and consequently moisture will only be sparingly required as a medium state in this respect is now preferable. Give the utmost diligence to the watering of the plants at this season, and particularly to plants which are plunged in fermenting beds where but little heat exists, as in such places it is better to err on the right side by keeping them somewhat dry; an agreeable temperature of 80° at the roots is most consistent with the requirements if it can be preserved.

The plants in the fruiting department will throughout the winter months demand considerable attention, as a fair proportion of heat and moisture is absolutely necessary to furnish these fruits perfectly, and if there is a period in the whole year which above others tests the skill of the cultivator, it is that which intervenes between now and the end of March. A good light house is highly essential for this purpose, and the best adapted should therefore be employed. Let 70° rule as a standard temperature both by night and day, and, according to circumstances, it should be allowed to rise another 10° in the daytime and fall 5° at night under extreme external conditions out-of-doors. Keep a brisk bottom-heat of about 85°, and

liberally water with tepid manure-water whenever necessary. In dry and airy houses syringe overhead occasionally at shutting up time, at which the heat should be at 80° or 85°, avoiding to wet those fruits which are in flower, and particularly so in the case of such as are not well up in the foliage. Amongst the indispensables which are required in the cultivation of these is a plentiful supply of heated water, and the best means which we have found of procuring it is by having a tank made specially suitable for the hot-water pipes to pass through it. *G. T. Miles, Wycombe Abbey.*

KITCHEN GARDEN.

Owing to the damp atmosphere caused by the recent heavy rains the winter stores of Lettuces, Endive, &c., will require frequent supervision by the constant removal of all decaying matters, and a daily attention to the giving of air; they may also have free exposure when the air is fine and dry, but only the lights tilted up when dampness prevails. In severe weather protection must be afforded, which need not be removed during those alternations of frost and thaw which are more destructive than the mere severity of the frost alone. Cauliflower plants in frames will require attention by the removal of dead leaves and surface-stirring of the soil, which may or may not be dressed with soot and lime according as the necessity arises. Air must also be freely given in fine weather; the same remarks will apply to the plants under handlights, which should be as much exposed as possible, otherwise, owing to the mild weather, they will grow too succulent and tender to stand very severe frost. Now is a good time to pot roots of *Whitloof* and *Chicory*, and put a first batch into some erection where there is a tolerably warm temperature; that of a Mushroom-house is excellent for the purpose and the least trouble, because there they will have the necessary darkness and moisture, which would have to be secured in a light place by a fair supply of water at intervals and covering with mats to ensure the necessary darkness for blanching. Dandelion roots are sometimes treated in the same way, for the sake of the blanched leaves to mix with other materials for salading, and are considered very wholesome, especially in dyspeptic cases; the flavour, however, is not agreeable to all persons, being very much stronger than that of either the *Whitloof* or *Chicory*. Some strong roots of *Seakale* should be at once potted and introduced into heat. A 10-inch pot will hold nine strong roots, and these, when well grown, will make a fair-sized dish; the demand, therefore, must regulate the supply, and a sufficient number of pots must be put to work every week to meet it; the necessary blanching is secured by inverting a pot of the same size over the roots and covering them up with mats. The heat at command will be the best guide as to when it may be expected to be ready to cut; by the application of strong heat it may be ready in a fortnight, but three weeks will bring stronger heads, and a month stronger still. Tepid water should be administered daily if necessary, but the soil must not be allowed to get dry, or the Kale will be tough instead of succulent. And this reminds me that although forcing in the manner described is a most invaluable adjunct during the depth of winter, when such luxuries are best appreciated, they do not in tenderness and flavour come nearly to that which is grown on the old system of covering with large *Seakale* pots and fermented dung and leaves—this requires more time and it must have a fairly strong and steady (but by no means a violent) heat to bring it in by six weeks, if forced harder it will come weak and spindly and all but worthless. See therefore that such materials are undergoing a course of preparation for the purpose, and cover up with them a portion of the permanent beds as soon as the very violent heat is exhausted. *Rhubarb* will come under nearly the same treatment. Strong roots may be potted up and introduced from time to time as may be necessary, into a gentle heat. I have found under the stage in heated structures a very economical place, but it may also be grown in the same manner as *Seakale* by covering the crowns with large pots made with a broad lid for the convenience of examining, and throwing over them dung and leaves a sufficient depth over the pots to keep out frosts, but not to produce a very strong heat, as it comes very weak if forced hard, and it is better to be a longer time about to insure strong and nicely-coloured sticks. The early scarlet-stemmed varieties are good for potting for very early work, but the stronger-growing and larger-stemmed sorts are best for later purposes and slow forcing. We have hitherto been highly favoured as regards frost, but as it is never certain at this season, it is best to be prepared with the necessary protecting material for *Celery*, and if there appears to be a likelihood of frost of great severity, place some tiles or boards upon the forwardest *Endive* which is not tied up, and cover them over with litter or bracken, or both mixed, which is better. This will both preserve and blanch them for use. *John Cox, Kellaf.*

THE
Gardeners' Chronicle.

SATURDAY, NOVEMBER 24, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Nov. 26—Sale of Dutch Bulbs at Stevens' Rooms.
TUESDAY, Nov. 27 } Manchester Botanical and Horticultural
Society's Meeting.
WEDNESDAY, Nov. 28 } Sale of Hardy Plants and Bulbs at Stevens'
Rooms.
THURSDAY, Nov. 29—Sale of Orchids at Stevens' Rooms.
SATURDAY, Dec. 1—Sale of Dutch Bulbs at Stevens' Rooms.

FOR the present season, at any rate, we may dismiss the fear of the COLORADO BEETLE from our minds, but it will not be long ere we may be again vexed with the apprehension of this pernicious insect. Whether the scare, or panic, experienced last autumn was fully justified time will show; in the meantime some entomologists have endeavoured to allay our apprehensions. Mr. MCLACHLAN, at the Plymouth meeting of the British Association, plainly stated that the supposed danger was, in his opinion, exaggerated, and now we find the eminent entomologist of Liège, Dr. CANDÈZE, holding similar remarks in a paper read by him at a meeting of the Belgian Entomological Society held at Brussels on October 13, and from which we take the following:—

"The Minister for the Interior has just published a pamphlet (of which 20,000 impressions were made), intitled, *The Potato Pest, Doryphora decemlineata*. This publication is, as indicated on the title-page, an extract from a work by Mr. CHARLES RILEY, Entomologist for the State of Missouri.

"One cannot do otherwise than applaud the zeal shown by the Department of the Interior in forewarning the country against an insect noxious to a culture so important as that of the Potato. It is of incontestable utility to make known to the inhabitants of the country districts all which concern the habits, transformations, time of appearance, and especially the means of destruction of noxious insects, about which there still exists, even with the educated public, many false and ill-judged notions.

"Having said this, we must allow ourselves to make certain criticisms which are addressed to Mr. RILEY, the true author of the pamphlet, more than to the Minister for the Interior, who has only put him under his patronage, and given in our own country considerable publicity to his views. We have always thought, and we think now more than ever, that the fear of seeing the Doryphora become a pest on this side of the Atlantic is, if not chimerical, at least much exaggerated. The laws which have been passed, the ministerial circulars and official placards which have been spread everywhere, not only in this country, but also among our neighbours, tend to nothing else but as showing that the arrival of Doryphora in Europe would be as fatal as a new invasion of cholera, or the reappearance of the cattle-plague.

"But it is far from being so!

"Without offence to Mr. RILEY we are not able to dismiss the idea that his writings convey the impress of certain exaggerations, the more so because we know that the motion caused in Europe by the cries and alarms of this entomologist, have produced surprise in his own country. Let us hasten always to say that we hold for real the greater part of the reproaches heaped upon the insect in question. We do not regard them as merely scarecrows. Certainly not! No doubt the insect is noxious. Still it is well, we will even say it is prudent, not to fall into exaggeration on the other side, and until it has been demonstrated to us by incontestable figures that this 'terrible devastator,' this 'redoubtable pest' has been the only cause of the rise in price of Potatos in the markets of Philadelphia and New York, we will maintain a reserve as to certain stories from over the seas which even represent it as menacing the existence of this precious commodity.

"There is apparently no doubt of an increase in the price of Potatos at St. Louis during 1873; but the author himself, in his pamphlet, attributes it as much to suppression of culture as to the ravages of Doryphora, many farmers, he says, not daring to plant Potatos. Let us hope that St. Louis is the town in which Mr. RILEY resides and publishes his articles.

"Certainly the Minister for the Interior would be very much surprised if the publications of his department, by frightening the farmers without reason, produced the same result here next season.

"Another fault we find with this pamphlet is that of

extolling, for the destruction of the Doryphora, an agent of which the handling is most dangerous. Every one knows the grave accidents caused by Paris-green to those who breathe the dust; one is warned with just reason against its employment in industrial arts. Medical men have warmly disapproved its usage in the ornamentation of carpets and cloth. It is not then without surprise that we find it advised to powder the fields of Potatos with it broadcast, leaving its management in hundreds of inexperienced hands.

"It is a case in which the remedy is worse than the evil. Mr. RILEY assures us as a fact that arsenite of copper decomposes, and is not noxious once that it is deposited on the earth. But before that? He says that its judicious employment has no inconveniences. We are not of his opinion, and can we reckon on the judicious prudence of a farmer's boy to whom would be left, in most cases, the care of arsenicating the Potato fields?"

THROUGHOUT the Metropolitan Market district, and probably generally elsewhere, there is such a profusion of VEGETABLE PRODUCE that it is not remarkable to find growers complaining of the poor returns obtainable in the market, the prices now paid for Turnips, Cabbages, Savoys, Coleworts, &c., being so small as to be productive of anything but satisfaction; though the consumer has little cause for rejoicing at the prices he is called upon to pay. In the face of these facts it is still common to find writers and public speakers enlarging upon the desirability of greatly extending the area of land devoted to such cultivation, because we have now to purchase so largely from other sources. If we already produce garden crops in such abundance that their cultivation results in a doubtful profit to the grower, how far is it likely that an extended cultivation would prove a remedy? We usually purchase elsewhere products that are either not in season with us or cannot be cultivated at a profit in this uncertain climate. Potatos are an exception to the present marketable value of garden products, these have gone up with great rapidity, and are now selling at an average price of £10 per ton; this high rate, however, does not arise from a restricted cultivation of this popular root. The disease has to answer for the shortness of the crop, but if the crop had been sound and healthy the price would probably not have exceeded the fairly remunerative one of £6 per ton. It is noteworthy that the working classes of the metropolis constitute the largest vegetable consuming portion of the community, and therefore the state of the market largely hinges upon their willingness or capacity to buy. Bread, meat, Potatos and beer they will have, but the latter article forms such a formidable item of their weekly expenditure, and is productive of so much misery and privation, that there is little money available for the purchase of vegetables, except on Saturdays or early in the week. Were the working class section of the community more provident and the middlemen not so rapacious, the demand for garden vegetables would be immense, but until some permanent change is made in these habits, and retailers abate their inordinate charges, market gardeners may continue to cultivate crops and grumble at the small returns.

— Though TOBACCO is grown to some extent in BAHIA, and the crops of last season are reported as being very abundant, the preparation of the Tobacco for market is carried on in a most primitive manner. This is accounted for by the cultivation being confined to the poorer classes, who do not possess the means of properly drying and preparing it for a wider competition for the markets of the world, the bulk of it finding its way to Germany, in which country it is chiefly consumed. The country is described as being admirably adapted for Tobacco culture, and were it to be thoroughly taken in hand, and the drying process, which is a most important branch, carefully attended to, it is considered that the produce of Bahia would be little inferior to that of Havana.

— Professor SADEBECK, writing on the CULTIVATION AND PROPAGATION OF FERNS in the *Monatsschrift*, reports the successful raising of Marattia plants from spores. The prothallia were cut up when eight weeks old, in such a way, however, that each piece retained a part or the whole of one of the deeply indented bays on the margin of the prothallium, and the thick tissue of the latter was as equally divided as possible in cutting it up. In this way nearly the whole of the fragments gave birth to young plants in four to

six weeks, whereas otherwise, with the greatest care, six or eight months elapsed before the first frond appeared. This fact is all the more important, because hitherto the only way of propagating Marattias was from the "stipular scales" at the base of the fronds, which often in the most skilful hands is the work of a twelvemonth.

— A NEW KIND OF FIBRE seems of late to have been extracted from the American Aloe (*Agave americana*), namely, from the flower-spike, and not from the leaves, which is the usual source. It is described as being exceedingly strong, yet very fine and gossamer-like. It is used for making into lace, known as Aloe lace. The art of making the lace is said to be very difficult to learn, and the splitting of the fibre still more difficult, consequent upon obtaining the requisite fineness. This art is carried on to perfection only by the inhabitants of a few small Spanish islands. This Aloe lace is highly prized and commands fancy prices in America, but in this country it is scarcely, if at all, known. Considering the source from whence the fibre is obtained, namely, the flower-spike, and the scarcity of the flowering of the Aloe, it does not seem probable that it can ever become an article of trade. Indeed, the entire supply is estimated not to exceed £1000 annually.

— We learn that a seat at the Board of DIRECTORS of the WEST LONDON COMMERCIAL BANK, CHELSEA, rendered vacant a week or two back by the death of one of its oldest members, has been unanimously voted to Mr. GEO. DEAL, an active member of the firm of J. WEEKS & CO., Horticultural Engineers, Chelsea.

— The next meeting of the INSTITUTION OF SURVEYORS will be held on Monday evening, November 26, when a discussion will be introduced by Mr. CHRISTOPHER STAPPHENSON, on "The Pruning of Coniferous Trees." The chair to be taken at 8 o'clock.

— From the *Monatsschrift des Vereines zur Beförderung des Gartenbaues, &c.*, we learn that the fruit of *PYRUS PRUNIFOLIA* has the name of producing the best fruit wine (*obstwein* or fruit wine, in contradistinction to true *wine*, or wine of the Grape), of the Continent. The demand for it is so great that the price has risen to nearly double the price of ordinary Apple trees. It is exceedingly hardy, growing and fruiting well in the most exposed situations. It flowers late and thus escapes frost.

— The Council of the Scottish Horticultural Association have arranged for the awarding of the four prizes, offered by Mr. JOHN DOWNIE, for the best original plan of a flower garden. The competition is open to journeymen gardeners, members of the Association, and the plans are to be sent to the Secretary, under motto, by February 1, 1878, accompanied by a sealed envelope containing the competitor's name and address.

— The reader of an interesting paper on HYBRIDISATION at last meeting of the Scottish Horticultural Association was Mr. ROBERTSON MUNRO, of the Abercorn Nursery, Edinburgh, and not Mr. ROBERTSON BROWN, as inadvertently stated in our columns lately.

— We learn that the floral decorations at the BROMPTON ORATORY on the occasion of the Duke of NORFOLK's wedding were carried out by Mr. WILLS. Some of the finest *Nepenthes* were used in the decoration; one specimen, over 7 feet high—*Nepenthes Kafflesiana*—had over sixty fine pitchers on it; other specimens, nearly as large, of *Nepenthes Dominiana*, having large numbers of fine pitchers. *Odontoglossum Alexandrae* was used in quantity, and upwards of 2000 white *Camellia* blooms, besides large quantities of choice white flowers.

— We understand that Mr. JAMES DRUMMOND, gardener at Blair Drummond, has resigned his charge there. He has been a gardener fifty-nine years, forty-nine of which he has spent at Blair Drummond. During most of his time at Blair Drummond he has been a member of the committee of the Stirling Horticultural Society. He was also one of the founders of the Kilmadock and Kincardine Garden Society in 1837, and it has been pro-

FIG. 129.—PAVIA MACROSTACHYA. FLOWER-SPIKE AND LEAF NAT. SIZE. (SEE PAGE 653.)

posed to present him with his portrait or some other tangible token of respect, and his old friends and acquaintances are solicited to contribute in aid of the above. Subscriptions will be received by Mr. DANIEL KENNEDY, Slater, Doune, Perthshire.

— The following Orchids are in flower in the fine collection belonging to J. H. WILSON, Esq., Lee Hall, Gateacre, Liverpool, under the skilful care of Mr. GLOVER:—*Angræcum bilobum*, *Brassia brachiata*, *Cattleya labiata*, *C. marginata*, *C. Harrisoni*, *Cymbidium Mastersii*, *Cypripedium insigne*, *C. nivenum*, *C. barbatum*, *Dendrobium japonicum*, *Epidendrum elongatum*, *Lælia Perrinii*, *L. major*, *Lycaste Skinneri*, *Masdevallia amabilis*, *M. othodes*, *M. trochilus*, *Odontoglossum Blantii*, *O. cristatum*, *O. biconchense cristatum*, *Cervantesii*, *O. decora*, *O. Rossii*, *O. grande*, *O. Uro-Skinneri*, *O. Lindleyanum*, *O. Inseleyii*, *O. leopardinum*; *Oncidium crispum*, several—one plant four spikes, 105 flowers; *O. ornithorynchum*, *O. ornithorynchum majus*, twenty spikes, very fine; *O. pelicanum*, *O. Weltonii*, *O. xanthodon*, *O. tigrinum*, *O. flexuosum*, *O. cheiroporum*, *O. bicallosum cucullatum*, *O. virgatulum*, *O. cucullatum majus*; *Pleione Wallichiana*, *Lagenaria*, *Phalenopsis grandiflora*, *P. amabilis*, *P. rosea*, *Restrepia antioquiensis*.

— One of the prettiest of table-plants for use at this season of the year is the charming little scarlet-berried *RIVINA HUMILIS*, a capital instance of the successful culture of which we met with at Wimbledon House lately. Mr. OLLERHEAD strikes his cuttings in spring, shifts the plants on into 48's, and cuts them down three times during the season. By this means he gets good bushy plants, which produce berries with the greatest freedom. The elegant *Cyperus laxus* is also a favourite on the table at Wimbledon House.

— WINTER FLOWERING TREE CARNATIONS are a prime feature among the host of florists' flowers, so well cultivated by Mr. TURNER at Slough, and we were glad to see, on the occasion of a recent visit, that Mr. TURNER still has an eye to their improvement, and right well do such useful subjects deserve his best attention. He has a fine batch of seedlings from that fine flower Prince of Orange, which as regards the "grass" present a great variety of form and substance, and some good novelties are expected when they come into bloom. The most free-flowering variety Mr. TURNER has at present is Sir Garnet Wolseley, a bright crimson suffused with fawn. It is a nicely formed and pleasing flower, with a rare "cut-and-come-again" sort of habit.

— Those who grow the lovely spring-flowering white PINK LADY BLANCHE will be pleased to hear that Mr. TURNER has a new Continental variety which, as regards the qualities of floriferousness, size of flower and beauty of form, is in all respects a scarlet counterpart. Its name is A. ALEGATIÈRE, and the colour a bright scarlet. The habit of the plant is strong and robust, more resembling that of a Carnation than a Pink. Lady Blanche is a perfect gem, and so, indeed, is the new-comer.

— An experience of CHRYSANTHEMUM SHOWS tends to prove that unless special prizes are offered for them there is a tendency to neglect the cultivation of the reflexed Chrysanthemum, the incurved flowers being more highly prized for exhibition purposes. The reflexed varieties, which are represented by such flowers as Annie Salter, Beauté du Nord, Chevalier Damage, Christine, Crimson Velvet, Dr. Sharpe, Garibaldi, Golden Christine, Julia Lagravère, Progne, Snowflake, White Christine, and others on the whole produce blossoms more freely than do the incurved varieties—and exhibition plants consist mainly of the reflexed forms. More than that, a reflexed variety can be permitted to carry more blooms than one of the incurved forms, which is of importance from a decorative point of view. Then there are a few of the Anemone-flowered Chrysanthemums that are also excellent decoration subjects, such as Fair Margaret, Fleur de Marie, King of Anemones, Marginatum, Miss Margaret, Prince of Anemones, Rose Marguerite, and St. Margaret; and of the Pompon Anemones Antonius, Astrea, Calliope, Madame Montell, Mr. Astie, Reine des Anemones, Sidonie, and Dick Turpin. These all require to be well grown to have their lovely flowers in perfection. So late is the Chrysanthemum in flowering this year that they,

aided by the late-blooming Japanese varieties, will carry on the head of flower till the earliest of the spring flowers come forth to greet the opening early spring months. A letter just received from Lancashire states: "Chrysanthemums are very late here; it will be quite the middle of December before they are in flower."

— While looking through a greenhouse a few days since some sickly-looking SHOW PELARGONIUMS cut back in August last and repotted in September, according to the usual custom, struck the eye. Their sad condition illustrated the oft-repeated tale: they had been repotted in a heavy tenacious soil with an insufficiency of drainage; they had been treated to more water than was necessary, and they had been occupying a cold, draughty, and unless part of the house. Who could wonder that plants went wrong under such conditions? During the autumn months, and especially during November and December, large-flowered or show Pelargoniums require water but seldom, and it should not be given unless they absolutely require it. If the plants be out of reach of observation, a rap on the pot with the knuckle will soon demonstrate if water is required, as a hollow sound will be given forth. The plants require plenty of light also, and they do best on a raised stage near the glass. A valuable lesson can be learned at this season of the year from the growers of Pelargoniums for market, for they keep the plants fairly warm and near the glass, and never expose them to cold currents of air. It is at this time of the year, when the young growths are pliant, that a good "bottom," as it is termed, can be formed to the plants. This is done by first of all tying a strong piece of bast in the form of a band immediately under the rim of the pots. To this band the shoots are tied down, thus forming a framework of branches close to the pot. It is in this way that the skeletons of the fine examples of Pelargoniums seen at the shows are made. In tying down the shoots care must be taken not to snap them off, and the advantage in tying them at this season of the year is owing to the fact, that during the time the plants are kept in a fairly dry state, the shoots are more pliant. The plants should be in an airy house, with plenty of room in which to grow; and when a time of severe weather comes only sufficient fire-heat should be put on to keep out the frost.

— The DWARF FRENCH MARGOLD may be made useful for blooming in pots in an ordinary greenhouse during the autumn. Some plants in 24-pots are now carrying remarkable heads of bloom, the gold and crimson stripes being very striking and effective. If a few plants are kept pinched back a little in early summer, and then lifted, put into pots and put out under a shady wall till established, they would begin to put forth growth that would produce an abundance of bloom in October and November. The dwarf growing section of Margolds must be selected for the purpose. The tall growing kinds are not at all suitable. The Margold is keenly susceptible of frost, and when it threatens the plants should be in a temperature sufficiently high to be able to resist it.

— Gardeners who, having to keep up a supply of cut flowers through the winter, are on the look-out for really good and useful plants for such work, should make a note of TROPÆOLUM BALL OF FIRE. We met with it at Slough the other day, and Mr. TURNER praised it very highly on account of its extreme floriferousness bright colour and usefulness for bouquet-making by reason of its long flower-stalks. If grown up the roof in a warm greenhouse it flowers with the greatest freedom, and provides a colour not otherwise easily obtainable during the dull months. A variety called the Double Orange Scarlet is also a neat grower, and flowers with tolerable freedom, but though useful on the score of variety it is not to be compared with Ball of Fire, a really invaluable plant.

— The NATIVE COUNTRY OF THE ONION, according to Dr. REGEL (*Gartenflora*, 1877, p. 264) has been definitely determined to be the mountains of Central Asia. His son, M. ALBERT REGEL, collected bulbs of an Allium in the hills south of Kuldsha, which were distributed from the Botanic Garden of St. Petersburg under the name of Allium polyphyllum. It has since flowered at St. Petersburg, and Dr. REGEL regards it as the wild form of A. Cepa. It has long thin bulbs, and Dr. REGEL proposes calling it A. cepa sylvestris. Typical A.

Cepa has been found in a wild state in the Himalaya Mountains. The latter region, then, and the Thian Shan Mountains, may be accepted as the native country of the Onion.

— Among CHRYSANTHEMUMS deserving of culture as special decorative objects James Salter, a Japanese variety, takes a high place. The flowers are made up of ribbon-like petals of a clear lilac or mauve colour, folded over towards the centre in the form of a ball, and the particular colour is very soft and attractive. It is not only a free-flowering variety, but it blooms early as well, and there is little difficulty in having a succession to cut from.

— In the T-range at Kew many plants of interest and beauty are in flower. In the stove is LINUM TRIGYNUM, an old and valuable winter-flowering plant, bearing, on a small specimen, over a dozen large golden-yellow flowers. That it has a limited cultivation is surprising when the fine display it makes is considered. Red-spider has great affection for its soft light green foliage, but this enemy is easily disposed of by the usual methods. Near this we find a new and curious species of Pavonia, P. Wiotti, of which the epicalyx forms a striking and showy feature. It is composed of numerous linear bracteoles of bright red colour, and the longer overtop the black purple calyx and corolla, which they almost enclose. The leaves are oval, acuminate, and serrate, its habit is much the same as in *Abutilon*. *Aphelandra Portiana* is quite fiery, with a good show of orange-scarlet flowers. This genus is one of the most valuable in the order Acanthaceæ, whose flowers are far too fleeting as a rule; here, however, there is a close succession on the spike. *A. nitens*, with black-bronze foliage, will shortly be in bloom. Underneath, as if for the contrast of its silvery-barred foliage, stands a good specimen of *Dracæna Goldiana*, one of Mr. Bull's finest introductions. We are irresistibly drawn to compare the variegation with some of the finer forms of *Sanseveira guineensis*, to which, however, it is infinitely superior in that, and undoubtedly every other, particular. *Alpinia vittata*, Hort. Bull, has just flowered for the first time so far as it is known. The flowers are white and scarcely contribute much beauty, but enabling comparison to be made; it is found not referable to any named species. The name "vittata" is of course a horticultural reference to the beautifully variegated foliage. *Æchmea* (*Chevalieria*) *Veitchii*, recently figured in the *Botanical Magazine*, still continues in the same condition as for many weeks past, its flowers do not open, and are even suggestive of being cleistogamous, especially when, if we remember rightly, there is another species figured also with the flowers closed. Its beauty depends on the leafy scarlet bracts forming with the flowers a dense spike. In comparison with Pine-apple, being so nearly allied, and similar in many particulars, it excellently illustrates the formation of collective fruits. *Centrosolenia ænea* is yet another plant within a few feet requiring attention. It is suspended near the glass, where it forms a suitable basket plant. The leaves are ample, of bright bronze hue, underneath which are several pure white flowers. In the intermediate division we can but mention *Begonia fuchsoides*, one of the older and prettiest species, with another equally valuable winter flowering plant, *Plumbago rosea*. Here there is a great variety of Gesneraceæ, of which several distinct forms are in bloom. *Alloplectus peltatus*, Oliv., a new species from Costa Rica, contributed by the Messrs. VEITCH, is by far the most interesting, first from the leaves being peltate near the base, then on account of perhaps a more striking feature—the non-development of one of two opposite leaves. One of each pair is reduced almost to the size of a scale, though still having nearly the form of its fellows. The flowers are yellow, and appear chiefly in the axils of the lower leaves and on the older wood. A figure has been drawn for the *Botanical Magazine*. *Nerine flexuosa* and *N. crispata* have been effective in the cool division. The first is sometimes perhaps known as *N. undulata*, a synonym only for the latter. Plant with single stems of *Clivia Gardeni* are considerably ornamental. The flowers are often nearly obscured by the foliage when many stems grow in the same pot.

— Mr. A. LODGE, late foreman at Eden Hall, Penrith, has been appointed head gardener to Lord BROUGHAM, Brougham Hall, Westmoreland.

— The length of time that some tuberous roots and tuberised stems will retain their vitality is extraordinary, practically unlimited apparently in some of the plants inhabiting the dry regions of Africa and other countries. In fact it is difficult to kill some of them. We remember a herbarium specimen of the handsome *Lewisia rediviva*, which had been collected several years, and when it was transferred to the ground it revived and grew into a healthy plant. In the *Bullettino della Società Toscana di Orticoltura*, No. 2, 1877, it is recorded that Mr. SANMARTINI brought tubers of *Psarum alexandrioum*, Boiss., from Egypt in 1839, and put them into his herbarium. After his death the herbarium came into the possession of the University of Pisa, and in 1874 Prof. CARUEL, noticing that they appeared to have life in them still, had them put into the ground, and they developed into perfect plants. The case of *Narcissus monophyllus* (*Gardeners' Chronicle*, 1874 p. 307) is equally remarkable.

— The collection of bulbous plants cultivated by Messrs. E. G. HENDERSON & SON at the Pine-apple Nursery has lately been enriched by a consignment of about 2500 new bulbs from Ecuador, which includes many *Pyrolirions*, the beautiful scarlet-flowered *Stenomesson eucrosioides*, and the single *Tuberose*, *Polianthes tuberosa*, by no means a common plant now.

— The display of *CHRYSANTHEMUMS* AT VICTORIA PARK has never been better as regards the large-flowered varieties than it is this season, and the fact is the more remarkable, inasmuch as Mr. MCINTYRE, the Park Superintendent, has no convenience whatever for bringing them on under glass. The plants have to be grown out-of-doors, and virtually to be shown *al fresco* for the want of a suitable permanent structure to exhibit them in. The collection occupies its usual site, a strip of grass about 100 yards long, by the side of one of the paths, and protected by a canvas shed quite unworthy of the place and the plants, of which there are about 8000, consisting of 5000 large-flowered sorts and the remainder of *Pompons*. The last-named are not yet fully out, but of the former there is, in every sense, a grand show of blooms.

— As a striking instance of what can be accomplished in Rose culture by successful practice, we may mention that Mr. TURNER showed us the other day a batch of *Maréchal Niel*, specially grown for planting in conservatories, with a view to producing immediate effect. They were grafted soon after last Christmas, and have now, many of them, attained the height of 12 feet.

— Messrs. JAMES CARTER & Co. request us to state that they were awarded a Banksian Medal for the collection of Potatoes exhibited by them at the meeting of the Royal Horticultural Society on the 6th inst.

— Nurserymen have long felt the want of a neat, handy, and cheap ROSE AND TREE LABEL, that will last a fairly reasonable time, and we were glad to learn the other day from Mr. TURNER, of Slough, that a useful label of this kind has been introduced by the Waterproof Label Company, Canal Works, Willesden. They are made of various sizes and forms, of stout waterproof paper, with strong eyelets, and strung with waterproof twine. The sample before us measures 4 inches in length and 1 inch in width, and is written on with patent indelible ink, is stated to last about eight months, and even to stand boiling.

— The specimen of *AGAVE MIRADORENSIS* which Mr. CROUCHER mentioned in our columns some time ago as throwing up for flower has now got its spikes 6 feet through the roof, and though it has had to stand several degrees of frost is unhurt, and now expanding its flowers.

— The expenditure upon the Windsor Parks and Woods exceeds the income from them by nearly £20,000, the New Forest yields a profit of £1300, the Forest of Dean one of over £6000, the High Meadows Wood over £4000, Alice Holt over £1000, Woolmer Forest and Bere Wood, Hants, nearly a £1000; Parkhurst Woods, Isle of Wight, yield a profit of £148—the total receipts from THE ROYAL FORESTS, says the *Journal of Forestry*, being £33,129 os. 8d., the expenditure £18,519 10s. 2d. Windsor Forest, being entirely exceptional, is not in-

cluded in the foregoing total. Like our contemporary, we have no doubt that the revenue from the Crown Woods might, in course of time, be very materially increased, while the expenditure on Windsor Forest might probably be diminished, and the income increased without diminishing the beauty of the forest, the comfort of the Sovereign, or the pleasure of her subjects.

— Mr. JOHN PRATT KENDALL, who has been foreman for the past five years in the gardens of Downshire House, Roehampton, has been promoted to the position of head gardener at that place, *vice* Mr. J. BURDEN, resigned.

— The last number of the *Agricultural Student's Gazette* contains *inter alia* a short article on COMFREY (*Symphytum asperillum*), a plant becoming known as a forage plant, its great advantage being its enormous yield; and another on the manufacture of Tea in Assam, which contains some valuable information on the subject.

— According to a notification issued by the Government of India, Department of Revenue, Agriculture, and Commerce, dated Simla, August 31, 1877, the Government of India in 1870 offered a prize of £5000 to the inventor of the best machine or process for the preparation of the fibre of the *Böhmia nivea*, popularly known under the names of RHEEA, RAMIE, and CHINA-GRASS; and the terms on which machines would be admitted to competition were widely notified in India, in Europe, and in America. Many persons declared their intention to compete, but ultimately only one machine was actually brought to the place of trial. The machine, having been carefully tested at Saharanpur in the autumn of 1872, was found imperfect in some important respects, and the inventor was adjudged not entitled to the full reward. He was, however, presented with £1500 in consideration of the partial measure of success he had attained after great perseverance. This machine has not since been adapted by the inventor to practical use, and no improved process of preparing the fibre of the Rhea has been yet discovered by other persons. Meanwhile the demand for Rhea continues, and the conditions which induced the Government of India in 1870 to offer a prize remain substantially unchanged; and it is accordingly hereby notified that a reward of 50,000 rupees will be paid to the inventor of the best machine or process which will separate the bark and fibre from the stem, and the fibre from the bark of the *Böhmia nivea*. A smaller reward, not exceeding 10,000 rupees, will be given to the inventor of the next best machine or process, provided it is adjudged to possess merit, and to be capable without difficulty of adaptation to practical use. What is required is a machine or process capable of producing, by animal, water, or steam-power, a ton of dressed fibre of a quality which shall average in value not less than £45 per ton in the English market, at a total cost, including all processes of preparation and all needful allowance for wear and tear, of not more than £15 per ton, laid down at any port of shipment in India, and £30 in England, after payment of all the charges usual in trade before goods reach the hands of the manufacturer. The processes of preparation are to be understood to include all the operations required subsequent to the cutting of the stems from the plants in the field, until the fibre is in a condition fit to be packed for conveyance to the market. The machinery employed must be simple, strong, durable, and inexpensive, and should be suited for erection in the plantations where the Rhea is grown. It must be adapted for treatment of the fresh stems, as cut from the plant. The treatment of dried stems offers certain difficulties, and the fibre prepared from them must, moreover, always be much more costly than the fibre produced from green stems. Except during the hot dry weather preceding the rains in Upper India (where Rhea grows best), it is very difficult so to dry the stems that no fermentation or mildew shall occur. But during this season the stems are comparatively short and the crop poor and stunted, unless it is artificially irrigated, and such irrigation greatly increases the cost of cultivation. In the rainy season the plant is in fine condition, but at this season it is almost impossible to dry the stems in quantity without injuring the fibre, unless recourse be had to artificial means of desiccation, which greatly increase the cost of the material. It is, therefore, obvious that the attention of inventors should be given

to the discovery of a process for the treatment of the green stems. All notices of intention to compete and applications for information should be addressed to the Secretary to the Government of India, Department of Revenue, Agriculture, and Commerce, Calcutta. A limited quantity of Rhea will be grown in the Botanic Gardens, Calcutta, and persons desirous of testing their machines before entering them for public competition may obtain green stems in such quantities, from the Superintendent of the Gardens, through this Department.

— The UNIVERSITY OF CAMBRIDGE has this week known how to add to its own repute by conferring the honorary degree of Doctor of Laws on one of the most distinguished alumni that famous seat of learning ever had: we allude to Mr. DARWIN. Apart from his own individual work, no naturalist has exercised greater influence in stimulating thought and promoting original work in others.

— One of the leading novelties in flowers at the present time at the Pine-apple Nursery is a hybrid evergreen NERINE, the result of a cross between *N. flexuosa* and *N. rosea*. The flowers are of the size and shape of its first-named parent, but of the colour of *N. rosea*.

— Two of the best EVERGREEN CLIMBING PLANTS FOR A TOWN CONSERVATORY are *Cissus antarctica* and *C. rhomboidea*. The former is the well-known Kangaroo Vine, whose cordate, lanceolate, serrate leaves have a very effective appearance. *C. rhomboidea* has smaller trilobed leaves, of a dark glossy green above, and glabrous beneath. Both are highly ornamental subjects, and we noticed a nice stock of them in Messrs. E. G. HENDERSON & SON'S nursery the other day.

— There will shortly be a fine display of *BOUVARDIAS* at the Pine-apple Nursery. Messrs. E. G. HENDERSON & SON have from 2000 to 3000 plants coming into flower. They are dwarf and bushy, and were struck in February, planted out for the summer's growth, and potted up during the first week in September. The principal varieties grown are *Vreelandi*, *elegans*, *longiflora flammæa*, and *Humboldtii corymbiflora*, the latter of which is powerfully scented at night.

— Mr. ADAM YOUNG, lately gardener to Sir SIMON MACDONALD LOCKHART, of Lee, Lanarkshire, has been appointed gardener to the Earl of BREADALBANE at Taymouth Castle, Perthshire.

Home Correspondence.

Notes on Lilies.—As requested by you I send one or two notes of experience lately gained when planting Lilies. For many years past I have urged friends who grew Lilies to allow plenty of room for the roots, especially for pot Lilies. We had pots specially made, deep in proportion to their diameter, and some two years ago, wishing to plant Lilies at the side of lawn beds where there were many trees, which, while they gave shade and shelter, would pull from their soil, I copied the pots used by my neighbour and friend Dr. Bennett to plunge his Palm-trees in summer round his lawn, and sunk some of these in which had been planted bulbs of *L. auratum*, *L. Krameri*, and *L. canadense*. A few days back I took them up and found the roots much longer than even I expected; one not very large *L. auratum* bulb, when measured by a rod, showed exactly 4 feet from the top of the bulb to the end of the roots. This I think shows well that a great depth of soil is required to give Lily bulbs really fair play. If we could examine some of my friend Mr. McIntosh's giants, I suspect we should find some roots 6 feet long. Lilies are sometimes reprobated, especially *L. auratum*, with dying and not coming up; and it is said that, notwithstanding the vast numbers yearly imported from Japan, the number of bulbs in this country does not increase; if they do often die, they at least furnish ample means for the race being perpetuated. In 1871 I sowed in two not very large boxes *L. auratum* seed which we had saved, and placed these in the garden, where they had no attention beyond an occasional watering in dry weather, and a mat screen in very hot weather. I lately broke up these boxes in which some of the bulbs had this year flowered, and took out 200 fair-sized bulbs to plant, besides a lot of small ones. Again, in 1874 I sowed seed of *L. californicum*, a great favourite of mine, the most richly painted of all the

North American Lilies, in two large seed-pans, and have just potted or rather boxed about 200 bulbs from them, some of them very good ones. When potting Lilies it is curious to notice how, without any apparent cause, some bulbs of the same species, planted at the same time in the same soil, and subjected to the same after-treatment, are found much more thriving than others. Last year, owing to so much of my time having been taken up with other and much less pleasant horticultural work, I had to leave many of my Lilies unpotted. I now find the above differences much exaggerated, owing to the longer time my mischievous chief has had the power to act. In some pots all the bulbs are in perfect health, in others about half, in others most are dead. It is, of course, most unreasonable to expect, as some seem to do, that great Lily bulbs will go on flowering in perpetuity; after a certain time, under the most perfect conditions of health, they come to their natural end, in many cases leaving only offsets, such as require some years' growth before they can take their parent's full place. *George F. Wilson, Heatherbank, Weybridge Heath, Nov. 19.*

Arundo Donax (pp. 597, 628).—My experience agrees with that of Mr. Ellacombe. I have grown *Arundo Donax* for many years, and never seen it flower. The stalks, if not cut down, make young green shoots the next year from every joint, but these stalks usually become weak, and are, for the most part, blown down, so that I have never seen one which has gone on into a third year. *William Wickham, Binsted-Wyck, Alton, Nov. 19.*

Common v. Irish Ivy.—I entirely differ from your correspondent at p. 599, in reference to the superiority of the former kind of Ivy to the latter for many decorative purposes. For covering a large archway, for example, the common Ivy, as it is usually seen, could bear no comparison to the Irish for giving a fine coating of fine large green leaves to take the eye especially in winter. For covering a large stone or such as a ruin the common Ivy may be better, and this is about the only place I have seen the common sort superior. If the Irish Ivy would give too thick a coating of leaves on certain walls there is no doubt but a selection of the finer leaved kinds would repay the labour; this could be done too without inspecting the plants personally—by getting specimen average leaves from a respectable nurseryman who has a good selection. This plan I can recommend from having tried it. Your correspondent at p. 629 is, I think, rather too critical from a horticultural point of view, however accurate his remarks may be about where English Ivy begins and where Irish ends. Although Ivy differs very much in sporting, as well as other variation, still for different purposes I think varieties can be had sufficiently distinct to give each kind an independent character, if I may use that term. For example, a piece of wall here about 30 feet long a few years ago was planted with nine plants, five named kinds, and just now every one of them is sufficiently distinct to warrant them being used for different kinds of leafage. I will send you herewith a few of the leaves for your observation, each one near enough representing the clothing of the plant. The variety named *dentata* would give quite a distinct kind of covering; it might be heavy-looking, and perhaps at first would not be taken for an Ivy. This variety will sport into the common form at times, but by taking away such shoots the desired kind can easily be secured. For a great many purposes the variety named *palmeta* is a very good one, and is decidedly superior to the variety sold in the trade as Irish Ivy. The common wild Ivy differs very much in different places, and that no doubt to some extent is affected by the soil, as well as by the situation. *R. Mackellar.*

Fourcroya longæva.—A plant of *Fourcroya longæva* which flowered in Mr. Peacock's collection at the Alexandra Palace, has produced young plants on the branches of the flower-stalks in such quantities—over a thousand—that I thought it might interest some of your readers to know it. I never saw a *Fourcroya* produce seed yet, has any one else? The other species also produce young plants, but not in such quantities; they came out in clusters and racemes. The old plant is quite dead. *J. Croucher, gr. to J. T. Peacock, Esq., Sudbury House.*

The National Rose Society.—Your correspondent, "A. B.," has drawn a very mournful picture of the National Rose Society and its committee. Will you allow us to say it exists only in his imagination? In the first place no report has been issued, the notice that appeared in your paper having no official authority; and in the second the Committee never asked the exhibitors to take one penny less than the full amount due to them. All the exhibitors were paid in full, with the exception of five; and when the committee met at what was considered to be a private meeting, to decide as to how the deficit was to be made up, these five gentlemen most generously proposed to take 50 per cent. off their prize-money: but

we are firmly convinced that, with the exception of those immediately concerned, no single member of the committee had thought of, much less hinted at, so liberal an offer. *The Hon. Secretaries.*

Lasiandra macrantha floribunda.—This most useful plant for stove decoration at this season of the year is well grown at Lee Hall, Gateacre, Liverpool, and when grouped with the Orchids its deep lavender-coloured flowers are very showy and attractive. *A. O.*

Masdevallia floribunda and myriostigma.—Prof. Reichenbach in the *Gardeners' Chronicle* of the 17th inst. (p. 616) refers my *Masdevallia myriostigma*, as well as *M. Galeottiana* of Achille Richard, to *M. floribunda* of Lindley. In so doing the eminent orchidologist of Hamburg is perhaps right, but he might have noticed that I myself discussed the affinities of *M. floribunda* and *M. myriostigma*. Specimens from Leibold and from Galeotti were examined, and notable differences were seen between them and the living plant. My description of *M. floribunda* runs thus:—"A low-growing plant of 2–3 inches in height; its flowers not raised above the leaves; the calyx, not very open and comparatively small (*exiguus*), has a small number of reddish brown spots; the petals are of a pale rose with a small tooth on one of their margins and a little point on the truncate extremity. The labellum is white, with a large number of rose-coloured spots, and its edges are crenulated. It was brought from Xalapa by Leibold and by Harris. Galeotti gathered it in the neighbourhood of Vera Cruz, No. 5075." The living plant I had before me, and which was well cultivated, attains ten centimetres in height (nearly 4 inches), and its flowers are conspicuously raised above the foliage; the calyx widely open is dotted over with an infinite number of small reddish-brown spots; the petals are white, notched at the summit, the lyre-shaped lip is uniformly white. The plant was brought in a living condition from Cordova by M. Omer de Malzine, and it was successfully grown by MM. Jacob-Makoy. Time will show whether the plants of Lindley, of Galeotti, and of Malzine, belong really to one and the same species. At the present time only one or two *Masdevallias* are known from Mexico, and the only species in cultivation from that country is the one just described. I do not undertake to enter into any controversy with M. Reichenbach on matters connected with Orchids—that ground is his, but it is permissible for me to glean here and there after the harvest of the proprietor. I have in Belgium several friends who are ardent Orchidophiles—MM. Jacob-Makoy, Oscar Lamarche de Rossius, Ferdinand and Dieudonné Massange, of Louvrex, Ferdinand Kegeljan, &c. Sometimes a newly introduced plant flowers in the collection of one or other of these gentlemen which it is not possible always to refer with certainty to described species, or it may be that the species are described in an imperfect or fantastic manner. If perchance I fall into error under such circumstances, I shall receive with deference the instruction of a specialist like M. Reichenbach, but the art of instruction demands absolute veracity, and is also quite consistent with courtesy. M. Reichenbach criticises the plate published in the *Belgique Horticole*, and contests its accuracy. In that he is mistaken; our draughtsman has not the talent of Fitch, but he is always to be depended on (*louisjours de bonne foi*). I assert that the representation is true to Nature, and my affirmation is corroborated by that of MM. Jacob-Makoy and O. Lamarche. Every year since 1873 *Masdevallia myriostigma* has flowered with these gentlemen as it is figured in the *Belgique Horticole*. To see in this figure an umbel or a terminal corymb one must, if not blind, have a vision distorted by imagination. If, as M. Reichenbach asserts, the flowers figured differ entirely from those of *M. floribunda*, it is because my *M. myriostigma* differs from *M. floribunda*, and if this be so I have won my cause. The plates of the *Belgique Horticole* have, at least, the merit of faithfulness; they are drawn under my direction, by competent artists—Mlle. P. de Sartorius, M. de Tollenaere, or M. L. Stroobant. M. Reichenbach has also given me a little lesson in Greek: he has pointed out the correct orthography of the word *myriostigma*; I confounded the Greek letter σ with ϵ . On this head I have to express my acknowledgments. *Ed. Morren, Liège.*

Laurustinus and Arbutus Unedo.—As seaside plants for shrubberies the above are unsurpassed. All round the neighbourhood of Colwyn Bay, North Wales, and not many yards from the shore, they grow splendidly, and flower most profusely, the former are fast coming into bloom, and some plants noticed are beginning to present quite a white appearance. It is almost impossible to find a shoot on large bushes that has not a truss of bloom upon it. I might also make mention of *Escallonia macrantha* in a situation very much exposed to the winds and close to the shore,

growing and blooming as well as could be desired. *Wm. Bardney, Colwyn Bay, North Wales.*

Bones.—I read the article on the above subject by Mr. Forsyth, in your issue of November 10, with attention, and, I must add, with a good deal of astonishment. He says, if I understand him aright, that the reason generally given why bone-earth or bones produce "marvellous effects" on certain old pastures—that they restore what has been removed—is "nonsense." His train of reasoning about pasture lands not producing cheese, but only the grass on which the cows who gave the milk which made the cheese feed, is altogether beyond my comprehension. So far from the fact of bones supplying what has been carried off in the form of cheese being nonsense, it is ascertained scientific fact. I beg to draw Mr. Forsyth's attention to the following facts and figures. It has been calculated that the average yield of cow's milk off good pasture land is equal to 750 gallons a year (Professor Johnston), and that every 10 gallons contain enough bone-forming matter to yield 7 ounces of dry bone. Hence, the milk of one cow removes equal to 33 lb. of dry bone in one year. Let us say that this is taken from 1 acre—or any extent whatever—but this is very near the truth, and is handy: then add to this the bones of one calf, which is equal to 10 lb. on an average; then one cow removes yearly from 1 acre of land as much bone-earth (chiefly calcium phosphate) as is contained in 50 lb. of bone-dust, calculating the amount of moisture contained in the bone-dust. By this means bone-earth equal to what is contained in 1 ton of bones is removed every forty-five years off 1 imperial acre, or 1 ton of calcium phosphate once in a century. Now in order to prove that the addition of bones exhausted pasture lands (thereby causing luxuriant growth in place of comparative barrenness) owes its "marvellous effect" to replacement of what had been removed in the cheese, is "nonsense," Mr. Forsyth must show that it is all a mistake about milk containing calcium phosphate (bone-earth), or that soils contain it in inexhaustible abundance. And he has got to show that its presence is a matter of indifference to the growth of the grasses. I considered it fully proved that the reason of pastures failing to produce cheese-yielding grasses (the term cannot be applied to all grasses) was owing to the failing supplies of bone-earth, as these peculiar grasses required it as an essential to their well-doing, and I had held it fully proved that the artificial application of it was the cause of the "marvellous" growth of which your correspondent speaks. Will your correspondent enlighten my ignorance? Will he show me how pastures can go on yielding grass which will yield cheese when the essentials are not forthcoming? *A. H. H.*

Gladiolus or Gladiolus.—Not so very long ago I was taken to task by an eminent classical scholar and dignitary of the Church for pronouncing *Gladiolus*, as Mr. Grindon directs us, viz., *Gladiolus*. I was told the only admissible way was *Gladiolus*. Who is right? *H. Harpur-Crewe.* [The dictionaries and grammars make it *Gladiolus*, but Mr. Grindon was following popular usage probably. Eds.]

Mushroom Spawn.—One hears of patent, selected, improved, Milltrack, Cutbush's, &c. We have tried all sorts, but for many years found nothing to equal the Milltrack; and have a bed in bearing just now that surpasses anything we have had before both in quantity and quality. As the proof of the pudding is in the eating, I send you a dish for your opinion. *W. Hill, Rich Hall Gardens, Nov. 13.* [Very good indeed. Eds.]

Germination of the Parsnip Chervil.—As no practical gardener has replied to Mr. P. Barr's inquiry (see p. 566), I will tell him what I know. Being in want some time back of some information respecting the vital force of the seeds of different commonly cultivated plants, I applied to my friend Mr. Stenger; I asked for the period, or number of years, that various ordinary vegetable and flower seeds retained their germinating power, and were regarded as "good" for sale. Through him the firm of Vilmoisin-Andrieux of Paris, kindly forwarded me the information I needed. Among other seeds mentioned was that of the tuberous Chervil: respecting this the writer says "it must be sown (new) in September or October, to grow in the spring, and it lies four to five months in the ground without giving any sign of life." *W. B. Hemslay.*

The Euphorbias.—These plants inhabit a large area, being found in different parts of the world, and comprise a very large number of species and varieties. There is one very common in gardens known as Milkwort, and also a few others of a hardy nature are cultivated. They produce generally very small flowers, the inflorescence being not very attractive in many kinds, but some are very interesting and

showy, such as *E. splendens*, *Bojeri*, *Jacquiniflora*, &c. The large-growing succulent kinds are cultivated chiefly for their odd and strange appearance—as some are very large, some very thin, others tall-growing, branching and spreading out in a remarkable manner, and many armed with very sharp spines or thorns, while others are dwarf and more compact. They are very interesting when grouped with other succulents, and are often mistaken for *Cactaceæ*. There are, I believe, many hundreds of species and varieties. They seed freely enough, and grow easily from seed, and the seedlings are quite distinct oftentimes from the parent plant producing it, hence so many kinds. I will just name a few very handsome kinds, large growers:—*E. polygona*, *abyssinica* or *grandis*, *arborea*, *natalensis*, and *officinalis*; *E. grandicornis* is very remarkable; and in dwarfs *E. Caput-Meduseæ* is very fine, and some others of the same character, and I cannot say but that all of them are more or less interesting to the cultivator. *J. S. Corderoy*.

Crotons.—*Croton Weismanni* is quite deserving of all you said of it in your last week's issue, as it is, without doubt, one of the very best of the old varieties, both as a show plant and for table decoration, purposes for which it is particularly adapted. Beautiful as this *Croton* is, however, it is quite eclipsed by one I saw at the Messrs. Veitch's a month or so back, named *Lord Derby*, which from its rich colour and fine form was conspicuous among a whole host of others and caught the eye immediately on entering. Not only was this the case with the large plants, but the smallest, even to fresh rooted cuttings, more especially bright in their markings, and so grand is it at all points that I have no doubt it will become a greater favourite than any. *C. Heertii* is likewise a very desirable variety, and one that should be in every stove. *J. S.*

Libertia ixiooides and grandiflora.—These are charming Iridaceous plants, and although generally treated as cool greenhouse or frame plants, are perfectly hardy. The flowers are pure white, well thrown up above the foliage, but rather sparingly produced for so vigorous a plant. The foliage is copious and densely tufted, of a very firm texture, and of the deepest possible green. It is perhaps the densely tufted habit of its fine foliage which constitutes the value of the plant, as a few plants of it will give a life and a freshness to the herbaceous border all through the winter—in fact I cannot call to mind any hardy herbaceous plant that carries through ever season such masses of fine evergreen foliage. The plants are allies of the *Sisyrinchium*s, but are far more persistent in all its parts than those plants. It is probable the plants may be known to some persons as "*Reanalmia*," as I have heard it erroneously called so. *Thos. Williams, Ormskirk*.

The Culture of Schizanthus.—I think many would-be cultivators are often deterred from attempting certain things by the too elaborate processes recommended. Now we do *Schizanthus* pretty well here, it is really a hardy annual, and there is usually quite heat enough for its germination anywhere in August. We usually sow it towards the end of the month in a cold frame, out-of-doors, or in fact anywhere; it is easy to raise, and as soon as the plants have become large enough to handle they are potted off singly into thumb-pots, shaded for about two days, and as soon as fairly established they are placed on a shelf as close as possible to the glass in a cold house, where they remain through the winter, getting a little water now and then to keep them from flagging. About the end of January or beginning of February they are soaked with water, and the next day they are potted into 6-inch (their flowering) pots. They want no water for several days, and by the time they do they have become re-established. They are such vigorous free-growing plants that from this onward all they want is plenty of air, light, water, and room. This latter is essential, for if they stand too close together, as soon as the sun begins to shine they grow so rapidly they will become drawn in a very few days. I have tried stopping them, but always fancied that a stopped plant bore no sort of comparison to one grown naturally—the latter a perfect candelabrum, the former, well, not so elegant. If they get the few essentials I have mentioned they will not require many sticks until they are fully in flower, as then they become a little top-heavy. I can fully endorse all your correspondent says about the value of the flowers for cutting purposes. We grow a stock of *pinatus* selected for many years, and comprising every shade of colour, from pure white with the most hieroglyphical markings all through to the deepest purple, almost black, with individual flowers nearly 1 inch in diameter. We usually have a row along each side of the central path of a span-roof house, and looking down it when they are in full bloom it has just the appearance of an avenue of butterflies (the markings of the flowers are much like those on the wings of some moths and butter-

flies). It would very much oblige me at least if your correspondent would give us short descriptions characteristic of the various species or varieties he mentions, as, in the case of any of them being distinct, I should like to add them to what I have. I have from time to time procured packets of seeds under various names, but in every case *Cæsar* and *Pompey* were much alike, and all had to go to the rubbish-heap. One curious fact should be noted—these *Schizanthus* are mostly covered with hairs, and each hair is tipped with a little globule of an intensely acid matter; so acid is this that to touch the tongue even slightly is sufficient to cause quite a sensation, and to this circumstance I attribute the plant's perfect immunity from insects. *T. Smith*. [Possibly it dissolves and digests the insects! as is found to be the case to some extent with other plants having hairs of a similar character. The *Schizanthus* is well done every year at Kew and at Chiswick. *Eds.*].

A Case for Carrying or Keeping Eggs.—Eggs are the most fragile of things, and to be carried or even stored safely they need to be packed in the most

FIG. 130.—EGG-CASE.

careful manner. Many devices have been used for this purpose, but although some of them have been found available for business purposes, none of them have been adapted to domestic uses for the storage of eggs. A "*Safety Egg-carrier*," devised and patented by *A. R. Sprout*, of *Lycoming Co., Pa.*, here illustrated, seems to meet both of these requirements in the most effective manner. Fig. 130 shows the box, with the trays, of which it contains eight, and holds altogether thirty-six dozen eggs. The eggs are held

FIG. 131.—TRAY FOR CARRYING EGGS.

in place by means of pins inserted in the bottom of each tray, and forming a circular supporting wall around each egg, as shown at fig. 131. Some soft material is wound around each pin, forming an elastic padding, by which the eggs are held firmly and securely. The trays, when filled, are placed in the package, one above the other, the bottom of one forming the cover of the one below it; the lid of the box holds all tightly in place. Small holes are bored through the bottom of each tray, the small end of each egg rests, and is thus held, in the position which is the best for long and safe keeping. Each tray of eggs may be inspected at any time, by holding it to the light to determine their soundness. For household use each tray forms an independent receptacle for eggs, the package or box being provided only for the purpose of the shipper or dealer. *American Agriculturist*.

Renovating Old Fruit Trees.—I beg to make a few remarks on your correspondent's admirable paper, p. 551. Although I do not agree with him in every point, yet it is a most interesting subject to me. First, as to manure, my impression is that it ought to be thoroughly incorporated with the soil, and to this end it should be moderately dry, so that it may be more easily and thoroughly mixed; of course some

judgment should be exercised not to use it in excess. Mulching is no doubt good in some soils and situations, but let it be given in addition to manure in the soil, or, if you practise "lifting" and mulch, use your mulching of the past one or two seasons for mixing with the soil. Sewage is a good manure, or, indeed, liquid manure of any description, especially in dry weather, but let it be in addition to the manure in the soil. I differ from some as to the state of decomposition of the manure when used, I prefer manure that not only acts as a fertiliser, but that helps to keep the soil open, and that the soil may not only be porous at the time of planting or lifting but remain so; I prefer dry weather, and I am very averse to treading the soil after planting or lifting, and may add that I have practised this with the very best results. I differ again as to the depth of soil, except for drainage, or to be used occasionally in lieu of the surface soil. I advocate keeping the roots near the surface—a depth of 2 feet I consider sufficient for large trees. Some of my trees that I practised "lifting" upon were between 20 and 30 feet high, with a spread of from 12 to 20 feet, and the deepest roots were only about 18 inches. The remark of your correspondent on root-pruning being done by some person "accustomed to it" is a most judicious one, "root-pruning and root mutilation are indeed two very different things." I, too, in lifting invariably leave some roots undisturbed; I, too, advocate doing it early. I make no remarks on Mr. Hind's paper, my own views are so in accordance with his that I cannot add anything to them. *George Lee, F.R.H.S.*

Verbena venosa.—It is somewhat remarkable that such a good old trusty bedding plant as *Verbena venosa* should now be so seldom seen, but with this, as with most other favourites—they have their day; and then get banished for a time, to return again and, if there is real merit attached, become more popular than ever as is the case with the above-named *Verbena*. I had it this season in beds on a terrace garden with others filled with *Purple King*, and the latter would bear no comparison to it either for constancy throughout or the display it made at any one time. During the whole season *V. venosa* was a mass of bloom, and so soft in colour as to form a pleasing contrast to the variegated *Pelargoniums* with which it was edged. Do what one will with *Purple King*, it is sure to become mildewed and shabby long before summer is over, but whether wet or dry *V. venosa* is always bright, and continues to bloom freely till cut down by the frost. Another advantage with it is that being nearly hardy there is little labour or room required to propagate and winter it, for if laid in leaf-soil, or the beds mulched with the same, they are quite secure, and may be increased in spring almost to any extent by dividing and cutting up the roots into lengths. Purple is a colour that cannot well be done without in a flower garden, and there is nothing better for affording it than *Verbena venosa*, except perhaps some of the *Violas*, and these do not succeed in light dry soils. *J. S.*

Root-pruning v. Finger-and-Thumb Pinching.—I have great pleasure in supplementing the latter part of Mr. Hind's letter at p. 597 with reference to pinching the shoots early or not at all. In taking charge of gardens a few years ago I found some pyramidal Pear and Apple trees in the enclosed kitchen garden, and my employer told me they had not borne fruit for years; and there were no fruit-bearing spurs on the trees. Why was that? it may be asked. My answer is—if fruit trees are allowed to grow at will during the summer months, and that growth is cut off in winter year after year, such fruit trees will produce very little fruit-bearing wood. My employer allowed me to do as I thought fit with the trees in question, after remarking that he had been recommended to have them root-pruned. Well, I adopted the finger-and-thumb pinching, with great success. The second year our trees were covered with bloom, and a good crop of fruit followed. I need not detail here the practice of pinching, because it is described in the *Gardeners' Chronicle* every year. I may as well say that I did not confine myself to Pear and Apple trees, but extended the practice to wall and young standard Plum trees with the same success. I am unable to understand why this system of pruning is not more practised. It is advocated year after year; yet on looking round neighbouring gardens I find it is seldom followed, the general plan being to cut off the summer's growth at the end of August, which, in my opinion, is of no use whatever in producing fruitfulness. I agree with your correspondent, Mr. Lee (p. 596), that if "*F.*" (p. 521), thinks that root-pruning in autumn will in any way bring about maturity in the wood of past seasons he will find it a mistake, far better pinch the tops of the shoots off in early summer, and continue to do so all through the summer months, when I think your correspondent "*F.*" and others will not want to root-prune much, if at all. In taking charge of the gardens here a short time ago my employer told me I should find the fruit trees very much neglected, and I am sorry to say

it was so. Here again I have another opportunity of introducing finger-and-thumb pinching to bring about fruitfulness, for I find very little fruit-bearing wood; but, on the other hand, long naked wood fit to make walking-sticks with, scarcely a spur on some of the shoots of the pyramidal Pear-trees, which are large and in good health. If you would like to hear of the results in the present case, I shall have pleasure in forwarding them in due course. [Please do so. Eds.] My motto is "Prune in summer for fruit, and in winter for wood." R. Smith.

On Covering Early Vine Borders.—I notice at p. 598 the letter of "S. W.," whose ideas are quite in keeping with my own. I have never yet been able to see the use of placing upon Vine borders a quantity of material such as is so generally used, but in point of fact I consider it does a great deal of harm. I think few gardeners would be so bold as to say that it could possibly do any good to heat the surface of the border to the depth of only a few inches, and have the remaining 2 feet or so quite cold and wet. And I fancy it would also puzzle them to tell us how we were to heat the whole 2 feet 6 inches through by placing fermenting material on the top without roasting or boiling the roots nearest the surface. Some years ago, when foreman in a nobleman's garden a few miles from London, where Vines were forced early, I had frequent arguments with the head gardener on the subject of placing heating materials on the border, he being strongly in favour of, and I just as strongly against, the system. At length, however, he gave his consent for me to try one year without it: I did so, simply placing on the Vine border a good covering of leaves, and over them a thin covering of straw to prevent the leaves being blown away. The Vines were started in the second week in November as usual; and we commenced to cut from them in the first week in May, just the same as we had done in former years, but with this difference, that the berries were both larger and much better coloured. Still for all that he refused to be convinced, only admitting that they certainly seemed to do as well without the manure as with it, and attributed the fact of the improvement in the size and colour of the berries to my having taken more care with regard to the ventilation, &c. Some years after, when I went to my first situation as head gardener, I found the vineries (two in number) in anything but first-class condition. They had not been used as early and late, but had both been allowed to come in together, so that in order to have the supply of Grapes extended over a more lengthened period I decided to make one an early house. Accordingly, I provided as many wooden shutters as, together with some spare sashes not then in use, would cover the border of the house intended to be started first. This I did in the early part of October, in order to protect the border from the cold rains of autumn, and in the last week of November I took them off, put on leaves and a slight covering of straw, and pruned and started the Vines. I cut the first bunches on April 28, being a week in advance of a neighbouring gardener who started his early house at the same time and who used fermenting material, and had the advantage of having forced the same house several times before. I continued to do the same thing for several years, until an addition to our flower garden compelled me to keep my vinery cooler, in order to suit bedding plants. These two instances I think go far to prove that fermenting material is not an absolute necessity, on a Vine border in order to produce early Grapes. I attach more importance, however, to keeping the cold rains of autumn off the border, either by means of shutters resting on bricks or something of the kind, especially in the case of young Vines. When Vines three and four years old are growing very strong and robust, there is even a greater danger than when not making such vigorous growth, because the roots they make late in the summer will be thick and fleshy, something like quills, and unless protected from the cold rains of autumn and early winter will nearly every one rot off, and when the Vines are started they will be found unequal to the task required of them on account of the loss they have sustained. The consequence is, they struggle on in some sort of a way until they get to the stoning period, which half of them never get through satisfactorily, and in the end they never swell to anything like their proper size; something like one-third of the bunches have a large number of shanked berries, and none of them colour as they ought to do. People wonder how it is—"such splendid wood that they made last year," and this year "such poor fruit." G.

Do Roots Digest?—May I offer a few remarks on the interesting letter of "Observer" in your last issue? The exudation of carbon dioxide by the roots is thus referred to in the English translation of Sachs' *Lehrbuch*, p. 625:—"This power of the roots of taking up, by means of the acid sap which permeates the walls of even their superficial cells, substances which are insoluble in pure water, presents itself in an

extremely evident manner, as I was the first to show, when polished plates of marble, dolomite, or osteolite (calcium phosphate) are covered with sand to the depth of a few inches, and seeds are then sown in the sand. The roots which strike downwards soon meet the polished surface of the mineral, and grow upon and in close contact with it. After a few days an impression of the root-system is found corroded in rough lines into the smooth surface; every root has dissolved at the points of contact a small portion of the mineral by means of the acid-water which permeates its outer cell-walls." I have little doubt that Sachs, by using sand, meant to exclude carbonaceous matter from the experimental soil. The useful word "digest" has unfortunately of late become ambiguous in physiological writings, having at one time the chemical connotation of solution by excreted fluids, at another the meaning of assimilation, a very different matter. Must we cease to use it altogether? As I am particularly interested just now in questions of plant-nutrition I shall be glad if "Observer" will communicate directly with G. S. Boulker, *Hemel Hempstead, Herts.*

The Best Winter Cucumber.—I can fully endorse all Mr. Batters has said in reference to Telegraph Cucumber (p. 565), especially for winter work, and I am sure the details of his method of growing it would be interesting, especially as they only have 2 or 3 inches in depth of soil to grow in. I should have no hesitation in adopting his method if I had to supply Cucumbers in winter. The last time I saw the Cucumbers at Chilworth Manor they had just passed through the dull months of winter, and were quite healthy and full of fruit. O. Orpet, *Further Barton, Cirencester.*

Temperature of Outside Early Vine Borders.—In reviving the discussion of last winter on this subject "S. W." seems to think the application of heat to outside early forced borders as "productive of more harm than good"; that "bottom-heat is a mistake," and that "roots simply respond to the call made on them by the application of heat to their tops in the way they do after spring fairly sets in," and that "Vines that are started early every year are prepared for it, as they get part of their season's rest while others are in active growth, and therefore require no extra inducement to get them to start." It appears to me the question here crops up, Does Nature supply bottom-heat to plants started naturally with the advent of spring and summer? And if so, how much and in what proportion? Last winter I averaged the mean temperature of the soil at 1 foot in depth, as taken from records at Dunrobin, Sutherland, and Thirlestane Castle, Berwickshire, for the years 1874 and 1875. The monthly mean over the two years will give a fair average for Scotland, and will give us something in the way of hard facts as a reply to the foregoing questions. The figures were given in the *Gardener's Chronicle* for February 10, but for convenience I may be allowed to note them here:—

Natural Mean Temperature of the Soil at 1 Foot Depth.

January	35.1	July	59.4
February	35.2	August	58.0
March	38.7	September	54.2
April	45.1	October	47.2
May	50.2	November	40.2
June	55.8	December	34.6

From these figures it will be seen that Nature does not call upon roots to "respond to the call made upon them by the application of heat to the tops," without at the same time providing a substantial and progressive increase of heat in the soil to encourage and stimulate the action of the roots. Though the ground in spring appears cold and wet, still, with the advancing year, Nature is steadily raising the temperature of the earth up to the autumn time, when it steadily declines to a resting-point. I believe the rise of the temperature in the soil has as much to do with starting plant life in spring as the increase of heat to stem and branch. For comparison let us suppose two houses of Vines each with all their roots in an outside border, No. 1 to be started December 2, No. 2 to start naturally, say, April 1, and in each case to have been shut up and syringed, with sun-heat in the afternoons for a fortnight previous to starting. The annexed table will show the difference of temperature in the border without protection in each case.

Natural Mean Temperature of the Soil at 1 Foot Underground.

No. 2, started April 1.	No. 1, started Dec. 1.	Deficiency of heat in border No. 1.
1st month, April 45.1	1st month, Dec. 34.6	December .. 10.5
2d .. May 50.2	2d .. Jan. 35.1	January .. 15.1
3d .. June 55.8	3d .. Feb. 35.2	February .. 20.6
4th .. July 59.4	4th .. March 38.7	March .. 20.7
5th .. Aug. 58.0	5th .. April 45.1	April .. 12.9
6th .. Sept. 54.2	6th .. May 50.2	May .. 4.0

The deficiency of temperature in the border for the early house from the above figures is considerable, amounting

to 20°.6 and 20°.7 in February and March respectively, and that, too, at one of the most critical periods of the forcing. Although a slight covering of leaves or bracken might reduce the deficiency by a few degrees, still it would be almost expecting too much from the Vine to look for healthy root action with the roots in soil only a little above freezing point, and the stem, branch, and foliage luxuriating in a carefully regulated temperature, ranging from 60° to 80°. That fermenting material has been so long used, and is still used at nine places out of ten, for the purpose of heating early outside borders, is (considering the standard necessary to pass muster in these times) a strong argument in favour of its beneficial effects where carefully applied. When the fermenting material is allowed to overheat and so destroy the roots near the surface of the border, there can be no question as to its being "productive of more harm than good," but the abuse is no argument against the use of anything. We may as well discontinue the use of steam, because some one allowed it to accumulate in a boiler with the safety-valve tightly shut down till it burst and blew the work and its surroundings to atoms. It has been said, and I quite believe it, that several good men have grown early Grapes without heat applied to the outside border; I believe it to be a fact also that Paganini could fiddle with one string, but then most folks prefer to work with four. The gardener who puts fermenting material on his Vine border does so with the aim of giving the roots while at work out of their proper season as near as possible the same temperature in the soil as they would enjoy had Nature been allowed to take her course. In doing so he is following Nature's example, and is, in my opinion, in a fair way towards success. There is no reason for standing still and resting content with the litter covering, however, if we can find anything better calculated to serve the purpose, and more cleanly and less laborious; the best plan I have hitherto seen to secure this end was that adopted by our of our best fruit growers in a large establishment in the South. Rafter were fitted up over the border about 2 feet from the surface, spare sashes were then utilised, and the border covered with glass, a flow and return pipe being run along the front in connection with the pipes inside; this plan secures sun and air, it can be closed early in the afternoon and encloses the sun-heat to heat the border; spare heat from the boiler can be used for the same purpose. The border is heated in the same way as Nature does the work, viz., by a covering of warmer air; this seems to give most of the advantages of the old method of covering with litter without its disadvantages. It does away with the litter appearance objected to by some, is not so subject to over-heating, and is in every way a great improvement upon the old litter covering. D. M., *Dunrobin.*

Reports of Societies.

Southampton Horticultural: Nov. 16.—The first winter exhibition of this Society was held on Friday, the 16th inst., at the Victoria Skating Rink, Portland Terrace, and proved in every respect a greater success than even the most sanguine friends of the Society expected or anticipated, indeed so much so that there is no doubt but that the committee will in future always include a Chrysanthemum, fruit, and vegetable show in their annual arrangements. There was a keen competition in many of the classes, whilst others were all but nil; and another year the committee will do well to revise their schedule considerably, and instead of splitting it up into as many as thirty classes have but half the number with advanced prizes, and a still better show will probably result. In the open classes for the best collection of Chrysanthemums grown in pots, arranged in a space of 50 square feet, quality and general effect to be the leading feature, the 1st prize was awarded to Mr. E. Wills, gr. to Mrs. Pearce, Bassett; and the 2d to Mr. T. Avery, gr. to the Mayor (A. L. McCalmont, Esq.), Highfield; both collections being very meritorious considering how late Chrysanthemums are in blooming this season. In the nurserymen's class for eighteen plants, not less than nine varieties, there were but two entries, and the awards were Messrs. Jackson & Son, Kingston-on-Thames, 1st, and Mr. G. Pullinger, Shirley, 3d. In the gentlemen's gardeners' class for the same number there was but one entry, and the 1st prize was deservedly awarded them; they were shown by Mr. T. Avery. In the open class for twenty-four cut blooms, distinct, there were three entries; and the 1st prize went to Mr. Hennell, gr. to F. A. Davis, Esq., Kingston-on-Thames; this stand was so excellent that the judges were not content merely to award the 1st prize but also highly commended them. The best flowers were Empress of India, Elaine, Mrs. George Rundle, George Glenny, Chang, Oracle, and Fair Maid of Guernsey. The 2d award again went to Mr. T. Avery, for very good flowers. In the gentlemen's gardeners' class for twenty-four blooms, not less than twelve kinds, there were three entries, and the 1st award went to Mr. E. Wills; 2d, Mr. T. Avery; and 3d to

Mr. Badd, gr. to F. G. Dalgety, Esq., Lockerhy Hall. For group of miscellaneous plants, arranged in a space of 70 square feet, quality and general effect to be the leading feature, there were five entries, but Messrs. Jackson & Son were a long way ahead of all the other exhibitors, having some fine Crotons, Dracenas, Palms, and Japanese Chrysanthemums. The 2d prize went to Mr. E. Wills, and 3d to Mr. Ladhams, nurseryman, Shirley. In the classes for berried plants, Cyclamens and Primulas, there was nothing of particular merit, if we except the Primulas from Mr. Osborne, gr. to H. T. Buchan, Esq., Wilton House, and the Cyclamens from Mr. Browning, gr. to F. Holloway, Esq., Marchwood Park.

For a Southampton show the display of fruit was excellent, and should induce the committee another year to offer more liberal prizes. All were open classes, and the 1st award "for six dishes of Apples and six dishes of Pears, six fruits of each," went to Mr. Browning; the 2d to Mr. Jones, gr. to Lady Barker Mill, Mottisfont Abbey; and the 3d to Mr. H. Vickery, gr. to Colonel Bruce, Testwood Park, Felton. There were seven competitors, and all showed exceedingly good fruit. In the class for three dishes of dessert Apples there were ten competitors, and in the class for a like number of kitchen Apples no fewer than twelve; and we may safely say there was not a bad dish in the lot, and many of superior merit. Grapes were but second-rate, though there was a goodly competition. Exhibitors in this class should make a note of how Grapes are shown at the London exhibitions, for if we except the 1st prize lots in each class—i.e., black and white—all had been terribly rubbed either by placing them on the stand or in taking them to the place of exhibition. In the class for "one Pine-apple," a magnificent fruit of Charlotte Rothschild was shown by Mr. H. Benham, gr. to H. J. Woods, Esq., Warnford Park, Bishops Waltham, a very good Queen by Mr. Browning, and a Smooth Cayenne by Mr. O. Batters, gr. to Mrs. Willis Fleming, Chilworth Manor, the awards going in the order named. In the class for three dishes of Pears there were seven competitors, and the first award was made to Mr. Browning, for excellent specimens of Duchesse d'Angoulême, Van M's Leon le Clerc, and Beurré Diel; 2d, Mr. Budd; 3d, Mr. Jones; and 4th, Mr. Avery. The latter gentleman showed also a fine collection of thirty-six varieties of Apples, not for competition, but they were deservedly awarded an extra prize. The display of vegetables was magnificent, as is always the case at Southampton. There were twelve competitors, all showing very excellent produce, and the awards went to Mr. H. Vickery, Mr. T. Avery, Mr. Batters, and Mr. Ams, in the order named. For collection of salading Mr. Batters took 1st honours, as he invariably does in this class; 2d, Mr. Browning; and 3d, Mr. Chard, Clarendon Park.

There were several extra awards made for groups of plants, the most noticeable being those shown by Mr. Ams, gr. to the President of the Society, the Hon. Eliot York, Netley Fort, and the group of Orchids shown by Mr. Osborne, gr. to H. J. Buchan, Esq., Wilton House, amongst which were specimens equal to those usually seen at the metropolitan shows. There were some most perfect specimens of wax flowers shown by Mrs. Fox, of Market Street, Brighton—so perfect that one required to look very closely to be certain as to whether they were not real. The exhibition was visited by all the *élite* of Southampton during the afternoon, and in the evening the place was crowded, so that we may safely congratulate the Society on having scored another success, which is due in no small measure to the energetic secretary, Mr. C. S. Fuidge. (From a Correspondent.)

Ealing District Chrysanthemum: Nov. 17.—The date of this exhibition was put on for a week owing to the tardiness of the plants to flower, and even with the postponement it was too early for some of the local cultivators. Compared with previous shows there was a decided falling off in plants in the competition classes, but the cut flowers were better than they have ever been before. Nevertheless, power should be given to the committee to exclude unworthy specimens; some should never have been admitted to such a show. In the gardeners' classes the best plants came from Mr. John Hart, gr. to T. Nye, Esq., Castle Bar Hill; and in the cottagers' classes Messrs. James Norcott and James Wilson exhibited some very creditable specimens. The best specimen Japanese Chrysanthemum in pot was James Salter, from G. S. Hinchcliff, Esq., of Acton.

In the leading class for twelve cut blooms, Mr. G. Lang was 1st, having capital examples of John Salter, White Globe, Venus, Beverley, Prince Alfred, Prince of Wales, Jardin des Plantes, Mrs. Dixon, White Venus, and Annie Holborn; 2d, Mr. T. Nye, with Miss Mary Morgan, Blush Queen, Prince Alfred, Guernsey Nugget, George Glenny, Jardin des Plantes, Lady Talfourd, and Isabella Bott; 3d, C. N. Peal, Esq. Mr. Lang was also 1st with six blooms of large flowering varieties, and six Japanese,

having in the latter case Fair Maid of Guernsey, Beaué Parfait, Magnum Bonum, Cossack, Elaine, and James Salter. Mr. Nye was 2d with three of the above named, and in addition Chang, Florence Nightingale, and Gloire de Toulouse.

In the classes for twelve bunches of Pompon varieties, Mr. J. Hart, gr. to T. Nye, Esq., staged some charming flowers, and was placed 1st in each case. The leading varieties were Madlle. Marthe, Adèle Pressit, Antonius, Marabout, Aigle d'Or, White Cedo Nulli, Madame Montels, and Madame Chalons. Messrs. C. Hutchings and C. N. Peal were placed equal 2d with some nice blooms. In one of the classes in which Mr. Hart exhibited, a special high commendation was given in addition to the 1st prize.

Messrs. Charles Lee & Son sent a very fine lot of Chrysanthemums in plants and cut blooms, grown at their Ealing nurseries by their manager, Mr. George Cameron. The plants carried remarkably good flowers. The leading varieties were:—James Salter, Elaine, Prince Alfred, Dr. Sharp, Gloria Mundi, Mrs. G. Rundle, Felicity, a beautiful reflexed white variety; Miss Mary Morgan, Fingal, and Prince of Anemones. The cut blooms comprised Dr. Sharp, Grand Lodge, Rival, James Salter, Queen of England, Virgin Queen, Gloria Mundi, Fair Maid of Guernsey, Gloire de Toulouse, Mr. Brunlees, Mrs. G. Rundle, Lady Margaret, Gluck, Annie Salter, Empress of India, Elaine, Bronze Jardin des Plantes, Prince of Wales, Cossack, Lady Talfourd, George Glenny, Cry Kang, Prince Alfred, White Beverley, and Beethoven. Mr. W. B. Smith, Ealing Dean Nursery, sent a collection of charming Cyclameas, and Mr. George Weeden some pretty Primulas.

The Right Hon. S. H. Walpole, M.P., the President of the Society, distributed the prizes in the afternoon, and advocated the holding of an exhibition of spring-flowering plants in a populous district like Ealing, where gardening was so generally followed. Steps have already been taken to give effect to this suggestion.

The Woolwich, Plumstead, and West Kent Chrysanthemum Society's annual show was held as usual on the 16th inst., and a very creditable little show was the result. For twelve cut blooms, incurved, grown under glass, Mr. E. Marshall was 1st with, amongst others, good blooms of Lord Derby, George Glenny, and Mrs. Dixon; the 2d in this class going to Mr. Hall, and the 3d to Mr. Colebrook, amongst whose exhibits were fine White Globe and Lady Hardinge. For six incurved Mr. Marshall was again 1st, Mr. J. Ams making a good 2d. Amongst their exhibits were good Prince of Wales, Prince Alfred, &c.

In the classes for outdoor culture, twelve Anemones gained Mr. R. Adams the prize, having good Acquisition, Lady Margaret, &c. Twelve incurved gained Mr. D. Spary like honours, as did also six incurved, showing fine Cherub, White Globe, Golden Beverley, &c. Good blooms of Golden Christine, Progne, Chevalier Damage, &c., gained Mr. E. Marshall another 1st for twelve reflexed; Mr. Spary was 2d, showing among others a good bloom of Captivation. Mr. R. Adams took 1st for twelve trusses of Pompons, having good Calliope, Antonius, &c. In the open class Mr. Tomalin, Crayford, gained the higher award for twelve incurved, his best blooms being Mr. Gladstone, St. Patrick, and General Slade.

In the classes for plants a well-flowered and trained G. Glenny gained Mr. T. Caines a 1st for a single dwarf trained specimen, Mr. Caines being also 1st for four and two dwarf Pompons, having good Mr. Astie, Mrs. Dix, Calliope, &c. Among the standards Mr. R. Adams was 1st for two, and Mr. E. Hall for four large flowered good plants of Peter the Great, Mrs. Sharp, &c., being exhibited. Mr. R. Adams was again to the front with four standard Pompons, having good Fanny, St. Thains, &c.; Mr. Hall making an excellent 2d. Mr. Caines was also the higher prize, taker for two and four pyramid Pompons, and for two standards Mr. Adams was 1st: in these exhibits we noticed good Fanny, President, Antonius, &c.

In the miscellaneous exhibits Mr. Cannell was awarded a special certificate of merit for a stand of twenty-four Pelargoniums, and also for Pelargonium New Life. Mr. Wright had a neat collection of Ferns, as also did Mr. Tomalin. Mr. Wright was also 1st for three and six ornamental-foilage plants, &c.

The Stoke Newington Chrysanthemum Society's Show was held on the same day as the above, and though the number of exhibits was comparatively small, the quality, especially of the good blooms, was far superior to any we had previously seen. Mr. Hammond, gr. to H. Hunt, Esq., Stamford Hill, was 1st for twelve blooms, with fine Mrs. Heales, White Venus, Nil Desperandum, Prince Alfred, &c.; the 2d being Mr. T. Beale, gr. to W. Laschelles, Esq., of Tottenham, with good Jardin des Plantes, John Salter, &c. In the various classes for six blooms the prizes fell to Mr. H. Butcher, gr. to F. P. Lambert, Esq., Stanstead Hill; Mr. C. Hammond, Mr. H. Butcher, and Mr. T. T. Godwin, Clapton, among

whose exhibits were good John Salter, Queen of England, White Globe, White Venus, and Prince of Wales. A half-dozen fine Elaine came from Mr. Oubridge; Mr. G. Landon showed twenty-four cut blooms, having in his collection good J. Dix, Dr. Brock, Princess Teck, Venus, &c.

The pot plants, though not so good as the cut blooms, were well bloomed, prizes falling to J. Monk, gr. to H. Heald, Esq., for six plants and for four plants. For four standards Mr. G. Landon, gr. to Dr. Monro, and Mr. F. Wills, gr. to A. Smece, Esq., were 1st in the various classes, as also was Mr. J. Monk for a collection of ten plants of Cyclameas. Decorative plants, Solanums, &c., were also exhibited.

The Borough of Hackney Chrysanthemum Society: Nov. 20 and 21.—This show was held at the Aquarium, Westminster, and was probably the best of the season, although the display, especially of cut blooms, was made to look rather meagre by the large amount of space allotted to the show. The plants made the most effective display. For six plants Mr. Hall was 1st, showing excellent Guernsey Nugget, Lady Hardinge, Faust, &c.; Mr. J. Rainbow, of Lower Clapton, being a very good 2d. For four plants Mr. J. Rainbow, jun., was 1st. For four Pompons Mr. Hall, Tulse Hill, was 1st: Mr. Benger, gr. to G. Fletch, Esq., Upper Clapton, making a good 2d, both staging very good plants. For four standards Mr. Benger was 1st, showing, amongst others, a good George Glenny, Venus, &c.; Mr. J. Holmes, gr. to J. Hicks, taking the 2d. Other good exhibits were staged by Messrs. Langdon, Batters, Sanderson, Pocock, &c. Messrs. E. G. Henderson, Pine-apple Nursery, had a good collection. Mr. Turner, Slough, was awarded an extra prize for group of grafted plants.

Messrs. Dixon, of Hackney, showed an interesting display of foliage plants and Chrysanthemums. For twelve blooms, Japanese, Mr. R. Adams, Plumstead, and Mr. C. Huggins were 1st; and Mr. J. Bryant, gr. to J. Stirling and Mr. Henderson 2d respectively, showing good blooms of Grandiflora, Bronze Dragon, Diamond, Jupiter, &c. Mr. Williams was 1st for twenty-four blooms, having White Globe, Nil Desperandum, Barbara, &c.; Mr. Holmes, South Hackney, being 2d, with White Globe, General Slade, &c. Mr. Langdon was 1st for twelve blooms, being well seconded by Mr. J. Holmes, gr. to J. Hicks, Esq. Among these exhibits were noticeable John Salter, Lady Hardinge, Hero of Stoke Newington, Mrs. Heales, &c. Six blooms placed Mr. J. Holmes 1st; Mr. Langdon taking 2d honours, showing good J. Dix, Barbara, Queen of England, &c. In the classes for amateurs Mr. W. Butters was 1st, showing Prince of Wales, Mrs. Heales, &c., Mr. C. Batters being placed 2d. In the open classes Mr. Sanderson gained 1st for twenty-four blooms with good Lady Morgan, Golden Eagle, Le Grand, J. Dix, &c. Mr. Sanderson was also 1st, for twelve and for six blooms, noticeable being Cherub, Lady Hardinge, Nonpareil, &c. Mr. Pocock also took 1st for six blooms, having Jardin des Plantes, Princess of Wales, &c.; Mr. J. Bryant, gr. to J. R. Stirling, Esq., Gunnersbury, making a good 2d. Many other exhibits gained much attention, but are not worth an extended notice.

Kingston and Surbiton Chrysanthemum Society: Nov. 21 and 22.—The first show of this Society was held in the Drill Hall, Kingston, and resulted in an excellent display. Mr. F. Wildman, Camberwell, was placed 1st for twenty-four cut blooms incurved, having fine examples of Prince Alfred, Mrs. Dixon, George Glenny, Queen of England; the 2d prize being well won by Mr. G. Cornhill, gr. to J. Virtue, Esq. For twelve incurved flowers Mr. Hinnell, Anglessea House, Surbiton, was 1st, and Mr. J. Bentley, gr. Edgcombe Hall, Wimbledon, 2d; in these exhibits were good examples of Mrs. Cunningham, Venus, Princess of Wales, &c. Mr. Nagle, Kingston, was 1st for six incurved, having, among others, fine blooms of Mrs. Cunningham and G. Glenny. For twenty-four Japanese, Mr. Hinnell was again 1st, with fine blooms of Bronze Dragon, Grandiflora, &c.; the 2d falling to Mr. Moorman, gr. to the Misses Christy, Kingston. Twelve fine blooms of Japanese gained first honours for Mr. Beckett, gr. Moor Place, Esher, the 2d going to Mr. McPherson: here we noticed in fine form Sultan, Striata, Oracle, &c. Mr. P. F. Sutton, Kingston, was fortunate among amateurs, being 1st for twelve blooms (Pompons excluded), and for six bunches of Pompons, with very good specimens. For twelve bunches of Pompons Mr. R. Press, of Kingston, was 1st. For twelve bunches of Pompons and twelve Anemones Mr. G. Masters, gr. to F. Day, Esq., Otland Park, and Mr. Cornhill, were 1st respectively: in their exhibits were good examples of Marabout, President, Princess Louise, &c.; and for twelve reflexed Mr. Moorman was 1st with Cloth of Gold, Blonde Beauty, &c.

The most noticeable features among the pot plants were the collections which gained Mr. W. Bates, Twickenham, 1st, and Mr. Moorman, 2d honours,

both showing very effective banks of finely flowered plants, noticeable among them being Gluck, Mrs. G. Rundle, Elaine, &c. The four dwarf-trained plants which gained Mr. Bexall a 1st prize were also good, Julia Lagravère, Hereward, &c., being noticeable. For six large-flowered Mr. E. Beckett, Esher, was 1st, and Mr. G. Cornhill 2d. In these exhibits were good Bronze Jardin des Plantes, Fingal, &c. Mr. G. Masters was 1st also for six dwarf-trained and four standard Pompons, with good Aurea, Cedo Nulli, &c. For six berried Solanums Mr. Beckett was again 1st, showing heavily berried plants of Capsicum Prince of Wales, Solanum picturatum, and Solanum Capsicastrum. The plants for table decoration and the fruit were fair, though not of extraordinary merit.

Fine banks of flowering and foliage plants were contributed by Messrs. Jackson & Son, nurserymen, Kingston, and Mr. Hinnell—Messrs. Jackson also showing stands of Chrysanthemums, &c., not for competition.

THE CHRYSANTHEMUMS AT SLOUGH.—Never since Mr. Turner included the Chrysanthemum amongst his florists' specialities has he had such a grand display as greets the visitor to his famous nursery at the present time; and it is a matter for regret that no favourable opportunity has been afforded for exhibiting a selection of them in town. Such being the case there is nothing for it but to go to Slough; the journey is not a long one, and an inspection of the flowers will amply repay a visit even from greater distances. Mr. Turner does not aim at getting the bulk of his collection in bloom at once, but rather to prolong the season as long as possible, by growing them in successive batches, so that from this time up to Christmas he may be able to meet the heavy requisitions made upon him for cut blooms for church decoration, and consequently any one going to Slough before the festive season comes round will be sure to find plenty of good things in bloom. For the cut bloom trade the white-flowered varieties are the most in demand, so that it does not surprise one to find these in by far the greatest abundance. The number of plants annually grown here has gradually crept up to the enormous number of 10,000, which quantity has been grown to meet this year's supply. The majority of the plants are grown on the natural system, in pots ranging from 6 to 8 inches in size, and by means of liberal culture a fine head of good blooms is obtained. A certain number of the plants are grown as standards, in which form a few would be useful in most places for standing about in conservatories. The plants are run up on single stems to the height of 2½ or 3 feet, and then grafted; and by careful handling are grown into heads from 18 to 24 feet through. The show-house is one of the best that could be devised for such a purpose—being a span-roofed structure 100 feet long and 14 feet wide—in fact the Rose-house, from which so many of the glories of Slough have gone out to do battle in the peaceful wars of the Roses. The plants are arranged in one gigantic bank with their faces to the north, and being kept down to a reasonable height, are easily seen without too much stretching of the neck from the path in front.

As we said before, the white-flowered varieties largely preponderate, consequently we make our selections from them first. Empress of India is of fine size and good build; Isabella Bott is a fine large flower, and tinted with rose; Mrs. G. Rundle, too well known for its purity and exquisitely incurved form to need comment; Mrs. George Parnell, a sport from the last-named, is considered superior to its parents by some growers, but here they were too nearly alike; Princess of Wales, a pretty rose-tinted flower; Queen of England, a fine bluish white; White Globe, a large incurved flower; and White Beverley, still one of the very best of the incurved section. A variety named Bridesmaid appears to be the same.

Amongst the coloured flowers we noticed a curiosity in Fingal, a purplish crimson flower, in the way of Prince Alfred, and the petals of which remain quilled for some time before opening. The best of the others still appear to be the well-known Bronze Jardin des Plantes, Dr. Sharpe, St. Patrick, a fine ruby red; Mr. Howe, a beautiful bronze, tipped with orange; Mount

Etna, also a fine red; Prince Alfred, Mrs. Brunlees, Grand Lodge Rival, brown, with orange centre; and the Golden Beverley, Golden Empress of India, Golden Queen of England, and Golden John Salter; Julia Lagravère, still maintains its own, and so does John Salter, cinnamon-red; Lady Hardinge, delicate rose; Guernsey Nugget, primrose-yellow; and George Glenay, the yellow sport from Mrs. Rundle.

Of the showy Japanese varieties Mr. Turner grows about three dozen sorts, most conspicuous amongst which were grand flowers of the large double-white early-flowering Elaine, and the equally fine white Fair Maid of Guernsey, the showy Gloire de Toulouse, rose, with a white centre, and worth classing with the very best; James Salter, a large and handsome lilac flower; To Kio, orange-scarlet, very showy; La Nymphe, rosy lilac, and very nice; The Daimio, pale pink, &c.

The Pompon section are unusually late this year almost everywhere, consequently but a very few of the four dozen varieties catalogued were to be seen in flower. Amongst these, however, we singled out three very fine things, which deserve all that can be said in their praise. The first one is Mr. Murray, a purple-flowered variety of a larger size than the ordinary run of Pompons, and an exceedingly nice flower; Mdlle. Marthe, a very handsome white; and Sœur Melanie, also a fine white, very free in habit, and early to boot. Mdlle. Marthe has the most perfect flower of the two, but for growing in quantity for cutting or for market work we most strongly commend Sœur Melanie.

VIOLAS.—During the past summer I have grown some twenty sorts of these useful bedding-plants, and send you the following notes, thinking they may be useful to some of your Northern readers, as, owing to the cooler summers, they grow and bloom better there than in the South of England. Generally, for bedding purposes, I hold that only distinct telling colours are requisite, and the following notes were entirely made with that aim in view.

Whites.—I grew White Swan, White Queen, White Bedder, and Mrs. Henry Pease (new); of these White Swan was the best, being very profuse in bloom, of good substance, close compact habit, and in colour a fairly good white. Mrs. Henry Pease is a stronger grower, but not so compact.

Yellows.—Golden Gem, Golden Perpetual, Cloth of Gold, and Crow Jewel, which last proved much the best; the habit is close and dense, flowers well formed, of good substance, and the colour a fine rich yellow; it is a free seeder, and should be carefully picked over, otherwise it will cease blooming.

Light Sulphur-Yellow or Straw Colour.—I only had Queen and Corisande, the latter a most telling colour; the habit is rather strong—to strop a grower for a front row or edging—but it blooms very freely, and the flowers are of fairly good form and substance.

Light Mauve.—Princess Teck, Hon. Miss Beaton (new), and Duchess of Sutherland (new); the two last are very much alike. Princess Teck, however, is my favourite, being of a beautiful compact habit—a very profuse and continuous bloomer—a novel and most telling colour. Either of the others are very good, and being stronger growers may prove most useful for the South.

Lilacs.—Enchantress, Perfection, Modesty, and Lilacina (Dean), the two last being much alike, but I prefer the last—it is a profuse and continuous bloomer, and a most excellent bedding plant.

Purples.—Forerunner (new), Waverley, Max Kolb (new), Duke of Edinburgh, and Bluebell. The last, better described as a light purple, is an excellent sort, a most profuse and continuous bloomer and a good compact grower. Forerunner, however, although more of a violet, is the most telling in this class, and must become a most popular sort; it is of good habit, a free bloomer, and the flowers are of good form and substance.

Blues.—Lothair, Royal Blue Pansy, Imperial Blue Pansy, and Royal Blue Viola (Dean). The last is a new and useful colour, being a really blue Viola. It is a free and continuous bloomer, perhaps the flowers are a little thio, but of good form; an excellent addition.

Darks.—Mulberry and Crimson Gem (new). This last is much the best of the two, and although the name is something of a misnomer, yet it is of a most pleasing light mulberry, with a fine yellow eye; is of good habit and blooms freely and continuously. However, in bedding arrangements this class can, as far as

I have yet seen, be well dispensed with; the colours are too dead and heavy for real bedding purposes, at any rate in the North, where there is a lack of bright subjects for bedding purposes (compared with the neighbourhood of London), where dull, heavy weather is much in the ascendant, and where something cheerful and bright from a horticultural point of view is indispensable. Y.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, NOV. 21, 1877.

Nov. 15.—Overcast and dull throughout. Thin rain fell. Mild.
 16.—A fine day, partially cloudy. Mild. Slight rain fell before 8 A.M.
 17.—A fine day. Gloomy and foggy at times.
 18.—A fine day. Cloudy till night, then cloudless.
 19.—Fine till noon. Overcast and wet from noon till 6 P.M. Fine after. Cloudless at night.
 20.—A fine bright day. Clear and cold.
 21.—Fine and bright till 11 A.M. Very cloudy and wet after.

LONDON: Barometer.—During the week ending Saturday, November 17, in the suburbs of London the reading of the barometer at the level of the sea decreased from 29.43 inches at the beginning of the week to 28.73 inches by 11 h. 40 m. P.M. on the 11th, rapidly increased to 30.33 inches by the morning of the 15th, decreased to 30.26 inches by the evening of the same day, increased to 30.45 inches by the evening of the 16th, and decreased to 30.30 inches by the end of the week. The mean reading for the week at sea level was 29.83 inches, being 0.13 inch above that of the preceding week, and 0.13 inch below the average.

Temperature.—The highest temperatures of the air observed by day varied from 58° on the 16th to 47½° on the 13th; the mean value for the week was 52½°. The lowest temperatures of the air observed by night ranged from 33¼° on the 17th to 46¼° on the 11th; the mean value for the week was 39¾°. The mean daily range of temperature of the air for the week was 12½°, the greatest range in the day being 16¾° on the 16th, and the least 6¼° on the 11th.

The mean daily temperatures of the air and the departures from their respective averages were as follows:—11th, 49°.6, +6°.4; 12th, 44°, +1°.1; 13th, 44°, +1°.3; 14th, 42°.8, +0°.3; 15th, 49°.4, +7°.1; 16th, 49°.2, +7°.0; 17th, 40°.9, -1°.1. The mean temperature of the air for the week was 45°.7, being 3°.2 above the average of sixty years.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 100° on the 12th, and 92½° on the 14th, and 77½° on the 16th; on the 11th the reading did not rise above 53°. The lowest readings of a thermometer on grass with its bulb exposed to the sky were 27¼° on the 17th, and 29¾° on the 14th; the mean value for the week was 34°.

Wind.—The direction of the wind was S.W., and its strength strong. The weather during the week was tolerably fine and mild, but the sky was generally cloudy. A violent gale of wind prevailed during the whole of the 11th and early morning hours of the 12th, when it suddenly dropped.

Rain fell on five days during the week, the amount collected was 1.01 inch.

ENGLAND: Temperature.—The highest tempera-

tures of the air observed by day were 63° at Plymouth, 61° at Eccles, and 60° at Liverpool and Leeds; the highest temperature at Wolverhampton was 56°, and at Leicester 56½°; the mean value from all stations was 58½°. The lowest temperatures of the air observed by night were 29½° at Eccles, 29½° at Wolverhampton, and 30° at Nottingham; the lowest temperature at Sunderland was 40°, and at both Brighton and Liverpool 38½°; the general mean from all stations was 34½°. The range of temperature in the week was the greatest at Eccles, 32°, and the least at Sunderland, 18°; the mean range from all stations was 24½°.

The mean of the seven high day temperatures was the highest at Truro, 56°, and Plymouth, 55½°; and the lowest at Hull, 49½°, and Leicester, 50½°; the mean from all stations was 52½°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 34½°, and at Nottingham, 37°; and the highest at Portsmouth, 43½°, and at Brighton, 43°; the mean value from all stations was 40½°. The mean daily range of temperature in the week was the greatest at Wolverhampton, 16½°, and the least at Sunderland, 9°; the mean daily range from all stations was 12½°.

The mean temperature of the air for the week from all stations was 46°, being 1½° lower than the value for the corresponding week in 1876. The highest were at Portsmouth, 48½°, Plymouth, 48°, and Brighton and Truro, both 47½°; and the lowest were at Wolverhampton, 42½°, and Hull, 44°.

Rain fell generally on five or six days in the week, but at Hull rain fell on one day only. The amounts measured varied from 2 inches at Plymouth and 1½ inch at Truro to two-tenths of an inch at Hull. The average fall over the country was three-quarters of an inch.

The weather during the week was generally fine and mild, but the sky cloudy. A violent gale of wind prevailed all over the country on the 11th inst., and resulted in great loss of property, and even loss of life in some parts.

SCOTLAND: Temperature.—The highest temperatures of the air observed by day varied from 59° at Leith to 54° at Paisley; the mean value from all stations was 56½°. The lowest temperatures of the air observed by night ranged from 33° at Dundee to 39° at both Glasgow and Greenock; the mean value from all stations was 37°. The mean range of temperature from all stations was 19½°.

The mean temperature of the air for the week from all stations was 45½°, being 1½° higher than the value for the corresponding week in 1876. The highest was 47½°, at Leith, and the lowest 41½°, at Dundee and Paisley.

Rain fell at Greenock to the amounts of 3½ inches, and at Paisley 3 inches were measured. At Dundee and Aberdeen four-tenths of an inch only was recorded. The average fall over the country was 1 inch and four-tenths.

DUBLIN.—The highest temperature of the air was 59°, the lowest 29½°, the range 29½°, the mean 45½°, and the fall of rain 0.70 inch.

JAMES GLAISHER.

Law Notes.

RAILWAY LIABILITY.—At the Bloomsbury County Court on the 16th inst. the case of the London and North-Western Railway Company against Dick Radclyffe and others was heard before Mr. Judge Russell, in which the company sued the defendants, horticulturists and seed merchants, carrying on business in High Holborn, to recover the sum of £4 odd, alleged to be due under the following circumstances:—

Mr. Harmsworth, who appeared as counsel for the plaintiffs, stated that the defendants in July, 1875, in attending an agricultural show at Manchester, forwarded a van containing a selection of articles intended for exhibition at the show by the Midland Railway to that place, and subsequently the same van was forwarded from Manchester to Leeds, where another show was to take place, at the termination of which the defendant expressly ordered the van in question to be forwarded to London by the plaintiff's line of railway.

The goods manager, the check clerk, and booking clerks from the Leeds station were then called, each of whom corroborated the learned counsel's statement as to the order given for forwarding the van to town by the London and North-Western Railway. This evidence, completing the case for the plaintiffs,

Mr. Charles Williams, who appeared as solicitor

for the defendants, urged there must have been a misapprehension on the part of the plaintiffs, as he should be in a position to prove by his client's evidence that no contract was entered into with the plaintiffs at all, but that the Midland Railway Company were the parties with whom the defendant had dealt throughout.

Mr. Dick Radclyffe, called, stated he never authorised his van to be sent by the plaintiffs' line, he had contracted with the Midland Company throughout the whole affair; his van had been shunted and left behind en route for Leeds at Huddersfield, and the company agreed to compensate him for the inconvenience he had been put to, and therefore he arranged with that company to return his van to London, and when he was asked by the station-master at Leeds if it was to go by the London and North-Western route, he distinctly told the official that he had arranged with the Midland Company; however, the van had been returned by the London and North-Western line, and he consequently refused to pay.

This being the defendant's case, the learned Judge said that looking to the probabilities of the case, he had no hesitation in ruling in favour of the defendant.

Mr. C. Williams applied for costs, which the Court awarded.

Judgment entered accordingly for the defendant, with costs.

Obituary.

ON Friday night, November 16, at his town residence, 14, Rutland Gate, Hyde Park, SEPTIMUS HOLMES GODSON, Esq., Barrister-at-Law, of Court House, Tenbury, Worcestershire, in his seventy-ninth year. Mr. Godson was one of the oldest Fellows of the Royal Horticultural Society, and a treacherous critic of its financial proceedings. He sat for many years at the Council board; and will be missed at the annual meetings of the Society.

Variorum.

COMPARATIVE ANATOMY AND THE HISTORY OF GERMS.—Systematic zoology and botany cannot today do without the theory of descent, because only by its light the mysterious relations of the numberless organic forms amongst each other can be really explained, i.e., reduced to mechanical causes, their similarity results as the natural consequence of inheritance from common parental forms, their variation as the necessary effect of adaptation to different conditions of life. Only by the theory of descent can the facts of paleontology, of chorology, and of oecology be explained in a way as simple as it is natural; only by this theory we understand the existence of the remarkable rudimentary organs, of eyes which do not see, the wings which do not fly, the muscles which do not move—nothing but useless parts of the body, which refute in the most emphatic manner the old-fashioned teleology, because they prove to the clearest manner that the utility in the structure of organic forms is neither general nor perfect; that it is not the result of a plan of creation worked with an object in view, but necessarily caused by the accidental coincidence of mechanical causes. . . . If the botanist followed the formation of the plant from the seed, the zoologist that of the animal from the ovum, they considered their morphological task accomplished by the perfect observation of the history of these germs. The greatest men in the domain of the history of evolution, Wolff, Baer, Remack, Schleiden, and the whole school of embryologists formed by them, understood by it, until a short time ago, the individual ontogeny exclusively. It is quite different to-day, when the mysteries of the wonderful history of germs confront us no longer as unintelligible riddles, but have clearly revealed their deep significance; because according to the laws of inheritance, the changes of form which the germ passes through in the shortest time, under our eyes, are a compressed and abbreviated repetition of the corresponding changes of form which the ancestors of the organism in question have passed through in the course of many millions of years. If to-day we place a hen's egg into the breeding-machine, and if twenty-one days later we see a little chicken creep from it, we no longer remain in mute astonishment at the wonderful changes which lead from the simple cell in the egg to the two-leaved gastrula, from this to the worm-shaped and skull-less germ, and thence to further germ-forms, which on the whole show the organisation of a fish, an amphibian, a reptile, and only lastly, that of a bird. On the contrary, we draw conclusions from this, regarding the corresponding series of forms of the ancestors, which have led from the unicellular amœba to the parental form of the gastrœa, and further on through the classes of worms, acephala, fishes, am-

phibia, reptiles, down to birds. The series of germ-forms of the chicken thus gives us a sketch of the series of its real ancestors. . . . Only by the critical consideration of the historical archives, by a speculation which is just as circumspect as it is daring, an approximate understanding here becomes indirectly possible. Phylogeny uses these historical archives in the same manner and according to the same method as other historical disciples do. Just as the historian, by the help of chronicles, biographies, and letters, draws up a detailed representation of an event long past; as the archaeologist by the study of inscriptions, pieces of sculpture, utensils, obtains the knowledge of the state of civilisation of a race long extinct; as the linguist by comparative investigation of all related living languages and their older written documents proves their development and origin from a common ancestral language, just in the same manner the naturalist of to-day, by the critical use of the phylogenetic archives, of comparative anatomy, ontogeny, and paleontology, arrives at an approximate understanding of the events which, in the course of unmeasured periods, have caused the change of forms in the organic life upon our globe. The history of the parental forms of organisms, or phylogeny, can therefore be proved by an exact method or by experiment just as little as this is the case with her older and more favoured sister geology. But the high scientific value of the latter is nevertheless now generally acknowledged. Only the ignorant to-day smile incredulously at the explanation that the colossal mountain chains of the Alps, the snow-covered summits of which we see glistening in the far distance, are nothing else but the hardened deposits of the sea. The structure of these stratified mountains and the nature of the fossils they enclose do not admit of another explanation; and yet it cannot be proved in an exact way. In the same manner all geologists now unanimously suppose a certain systematic succession of the mountain strata, corresponding to their different ages; and yet this system of strata is nowhere perfectly present upon the earth. But our phylogenetic hypotheses may claim the same value as is given to these generally recognised geological hypotheses. The only difference is that the enormous structure of hypotheses in geology is far more perfect, simple, and easier to understand than that of youthful phylogeny. From "The Present Position of the Evolution Theory," Address by Professor Haeckel at the Munich meeting of the German Association. "Nature," Oct. 4.

TACT.—A little tact often overcomes difficulties which much earnest endeavour fails to remove. Just as, a tiny bolt withdrawn, a gate opens which it would have taken many strong-armed men to cast down, so a word rightly spoken, though in itself a thing little enough, does that which volumes would not accomplish at another time. Tact is in no sense difficult of attainment; it needs, however, that its pupils should dispossess themselves of any self-opinionated manners, which make them contemptible and objectionable to others. If persons will persist in carrying with them an ungainly self-consciousness, a determination to be heard by every one, and to be believed in by every one, and to lord it over every one, they will soon be consigned to the limbo of unprepossessing and unpopular people, who forget that the outside world contains wiser and better people than themselves. Tact is quick to learn, quick to discern when it ought to be silent, as well as when it ought to speak. In this sense it is consistent with true humility, and with a wise recognition of individual imperfection. The victories of several of the greatest generals in history have been achieved by the sense of knowing when they were, for the time, beaten, and having the tact to retreat for the hour, and gather up their broken forces, rather than risk all upon a last struggle with superior strength; and some of the most successful statesmen have been characterised by a tact which knew how to speak right words at right seasons, who possess very slender powers of oratory indeed. Some there are who slight tact, because of its seeming lack of superiority over the endowments of others. They never like to overcome difficulties so much by skill as by force. A victory is nothing to them unless it be achieved by a hotly contested battle; a success loses its honour unless it be the result of strong competitive forces; but in reality they are mistaken, for in quiet skill there is as much manifestation of power as there is in hand-to-hand tussles with our peers. Some there are who not only depreciate tact, but positively despise it. They are, for the most part, what may be called plain-spoken persons, and a very offensive class they are. It is particularly obvious that they bruise people's feelings without compunction, and it is equally clear that they have a particular dislike to being themselves treated to homilies by other plain-spoken persons. They are happier as speakers than hearers! Tact! what do they care for tact?—they have truth to tell, and isn't it right to tell it? With suchlike sophisms they smother over the fact that even truth must be spoken in love, and that the how and when to speak it are amongst the most important considerations that can occupy the minds of kind and thoughtful persons. There is a tact

even in telling the most disagreeable truths, and that man is little to be envied who despises a skill which, whilst it preserves the manliness which dares to speak the truth, also preserves the gentleness which desires to spare the feelings. From "Cassell's New Popular Educator" for November.

Answers to Correspondents.

APIARY (BEE-SWAX): S. F. Conway. No. 2: Take the combs and boil them in a coarse bag. After simmering about half-an-hour press the wax out into a pan of cold water, then melt it in the oven in a saucer. All the dregs will settle to the bottom, the rest will be the best wax. No. 3: Make a syrup, 3 lb. of lump sugar and 1 1/2 lb. of water, just boiled to dissolve the sugar, and feed them on the top of the hive with a pickle-bottle, with a piece of muslin tied over the mouth.

ARE TODEAS TREE FERNS? E. Barrow. According to the accepted classification Todea superba is horticulturally a Tree Fern, since it occurs with erect woody stems of considerable height—2 feet at least.

BOOKS: C. D. E. Williams' Ornamental Stove and Greenhouse Plants (Williams, Victoria Nursery, Upper Holloway), of which there are two small volumes, one devoted to flowering plants, the other to foliage plants, will exactly suit you. These are for indoor plants. Thomson's Handbook of the Flower Garden will supply the information respecting outdoor plants. Neither of them are expensive.

CALANTHES: F. B., Ferndene. We do not for a moment suppose that the nature of the soil has anything to do with the diseased condition of the Calantid bulbs, from the fact of its having grown them fairly up to the point when disease began to show itself. The disease might be brought about by different means, the exact cause not being easy to hit upon without seeing the conditions under which they were grown, or fuller details. The most likely causes that occur to us are a soft condition of the growth brought about by a very humid atmosphere, insufficient air, and a position too far from the glass in the early stages of their growth, followed by a too moist state of the soil at the time the flower stems were about to appear, which has caused the roots (although these die annually) to decay before their time. The best examples of these we have ever had or seen were grown in shallow pans, suspended close to the roof; so treated the bulbs attained more than double their usual size, the biggest throwing up from three to four spikes each, often in addition to the two usually produced at the base, one or two from near the top as well. The largest spike from the base of one of these largest bulbs carried over a hundred and twenty flowers. They will grow in almost any description of soil, provided they get plenty of light, but, of course, must be slightly shaded from the sun.

CHRYSANTHEMUMS: N. W. See p. 562. Anticipated. CUCUMBERS: H. G. The general treatment appears to have been correct. We should think the fruit has suffered from a cold draught, which has checked their growth; or possibly from a chilling of the roots from the accidental use of cold water.

CHAMERANTHEMUM: Duffer. They are easily grown as stove herbaceous plants in a warm, moist pit, and increase readily by cuttings. They flower freely, and frequently bear fertile seed, by which they can also be increased.

FORCING LILACS: M. M. You should select good bushy plants of the common variety, pot them up, and force into flower in any hot, damp, and dark place.

HEATING: Duffer. If we understand your sketch, we would suggest as your best plan of accomplishing the object in view to distribute sufficient flow-pipe to heat the vinery, and then to add length enough of the return into the adjoining fernery to warm it to the temperature required.

HELIOTROPE: P. W. The seedling Heliotrope appears to be of a deep but bright purple, and forms a good-sized truss. Beyond this we can form no idea of its merit, as so much depends on habit and on its blooming properties. If you have present plants of it, you should send one to the next Floral Committee meeting at South Kensington, which will take place on December 4.

INSECTS: G. R. S. The caterpillar of the Goat Moth, Cossus ligniperda.—J. v. Volx. We found a few very minute, moderately active larvæ of a species of trips on your Anthurium leaf. Repeated fumigations are, we believe, the surest remedy. I. O. W.

LATE GRAPES: Derbyshire. The best late keeping black Grape is the Lady Downe's Seedling, but we should, for our own use, grow only the Black Hamburg and the White Muscat of Alexandria.

MARKET GARDENING: A. E. A. 1. Yes. If you invested the money judiciously and made the most of the ground. 2. It is impossible to answer this question without knowing more than you tell us. Very much depends upon the nature and quality of the ground, upon the measure of skill you can put into its management, and even upon the sort of things you can find a market for. 3 and 4. It is also impossible to answer these questions without knowing what you intend to grow, and the cost of labour in your district. 5. Cutbill on Market Gardening (Groombridge), brief but practical and trustworthy. You might also gain some useful hints from Burbridge's Horticulture, published in Stanford's Industrial series.

MELONS: C. Tyler. Melon "Pine Cream" was cer-

tificated at a meeting held at Chiswick on October 10, 1877.

NAMES OF PLANTS: H. M. K. Euconymus europæus.—E. E. E. The Bouvardia appears to be B. jasminoides, which, however, we have not at hand for comparison. 1, Selaginella Pouteri; 2, S. stenophylla. There was no No. 3.—H. G. Lomaria gibba.—M. R. 3, Cereus flagelliformis; 4, Opuntia microdasys.—Hayes. Bocconia cordata.—J. M. W. Arundo Donax.

POLYPODIUM VULGARE VARIETY: J. M. Your variety is a very good one, and apparently distinct. It might be called variable cristatum.

STEALING MUSHROOMS: J. M. asks, "If a person goes on another person's private ground and gathers Mushrooms, can he be prosecuted for stealing Mushrooms?" Yes, certainly; but we should prefer to prosecute for trespass.

TERMS OF ENGAGEMENT: W. B. 1, Yes. You ought to have had a copy of the agreement at the time of signing; 2, Yes. You will be legally entitled to a quarter's notice or a quarter's pay, if the agreement is stamped, but not otherwise.

* * * Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editors would also be obliged by such communications being sent as early in the week as possible. Correspondents sending newspapers should be careful to mark the paragraphs they wish us to see. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

CATALOGUES RECEIVED.—Messrs. Cranston & Co. (King's Acre, near Hereford), Descriptive Catalogue of Selected Roses, and Catalogue of Forest and Fruit Trees, Conifers, Shrubs, &c.—R. Dean (Ranelagh Road, Ealing, London, W.), Catalogue of Florists' Flowers, Potatos, &c.—Messrs. C. Verdier (28, Rue Baudricourt, Paris), Trade List of Gladiolus, Lilium and other Bulbs, also List of Roses, Trees and Shrubs.

DIED.—On the 15th inst., at his residence, Rochford, Essex, GEORGE WOOD, Esq., solicitor, aged seventy-three years. Friends will please accept this intimation.

Markets.

COVENT GARDEN, November 22.

There are no alterations to note this week, trade being still quiet, with a short supply. Late Grapes, such as Alicante and Lady Downe's, are putting in an appearance, and are only cleared at low prices. Cobs very quiet. James Webber, Wholesale Apple Market.

CUT FLOWERS.

Table with 2 columns: Item and Price. Includes Alutiflon, Azalea, Bouvardias, Calceolaria, Camellia blms., Carnations, Chrysanth, Cornflower, Epiphyllum, Eucharis, Gardenia, Heartsease, Heliotropes, Hyacinths, Jasmine, Mignonette, Narcissus, Pelargoniums, Primula, Pyrethrum, Roses, Staphaotus, Tropæolum, Tuberoses, Violets.

PLANTS IN POTS.

Table with 2 columns: Item and Price. Includes Azalea, Begonias, Bouvardias, Camellia, Chrysanth, Clematis, Coleus, Cyclamen, Cyperus, Dracæna terminalis, Erica Hyemalis, Euonymus, Ferns, Ficus elastica, Foliage Plants, Fuchsias, Liliums, Mignonette, Myrtles, Palms, Pelargonium, Solanums, Valotta purpur.

VEGETABLES.

Table with 2 columns: Item and Price. Includes Artichokes, Asparagus, Beans, Beet, Brussels Sprouts, Bush, Cabbages, Carrots, Cauliflowers, Celery, Chilis, Cucumbers, Endive, Batavian, Garlic, Herbs, Horse Radish, Leeks, Lettuce, Mint, Mushrooms, Onions, Parsley, Radishes, Spanish, New Jersey, Salsify, Sea-kale, Shallots, Spinach, Tomatos, Turnips, Potatos, Essex Regents, Kent Kidneys.

FRUIT.

Table with 2 columns: Item and Price. Includes Apples, Grapes, Lemons, Melons, Nuts, Cobs, Oraoges, Peaches, Pears, Fine-apples, Figs, Walnuts.

SEEDS.

LONDON: Nov. 21.—The seed markets have lately been better attended, and more disposition has been manifested to operate in Clover seeds. As regards red Clover the chief demand has run upon fine qualities, and for these holders in France are endeavouring to obtain more money. As yet there is no supply to hand of English red; for the few samples which have been shown no values have been fixed. At present there is no bulk of seed pressing from the United States; the American home demand has this season been unusually large, and as the growers there appear in no hurry to market their produce at the rates now current, no accumulation of stock at any of the western depots has taken place. At latest mail advices the supply in the important centre of Toledo was less than 2000 bags. The recent advance in Alsike is estimated at from £8 to £10 per ton. White Clovers have also lately hardened in value to the extent of 2s. to 3s. per cwt. In Trefoil there is for the moment scarcely any business doing. Mustard and Rape seed have moved off slowly on former currencies. The low quotations for Canary seed have induced a certain amount of speculative buying. Owing to the milder weather the sale for blue Peas has somewhat fallen off. Lised seed keeps steady. John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday, although there was perhaps more inquiry for certain classes of grain, there was an absence of life in the trade, and prices, which were under the influence of heavy foreign importations, showed no distinct tendency to recover. Indeed, as regards Wheat and flour, sales were here and there pressed, at some decline from the reduced prices of last week. Barley was well held, especially fine malting produce. Malt was dull on previous terms. Oats were a slow sale, while prices were as before. Maize realised the full prices of last week without difficulty. Beans and Peas were unaltered.—Trade on Wednesday was dull. No new feature presented itself. Unsettled weather and heavy foreign importations offered a certain check to business, and in the absence of any general pressure to sell quotations were much the same as on Monday. The tone as regards spring corn was moderately firm.—Average prices of corn for the week ending November 17:—Wheat, 55s. 8d.; Barley, 43s. 8d.; Oats, 24s. 9d. For the corresponding week last year:—Wheat, 48s. 1d.; Barley, 39s. 3d.; Oats, 25s. 5d.

CATTLE.

At the Metropolitan market on Monday there was a larger number of beasts on offer than for some time past; the quality, however, was, on the whole, inferior. Some few of choicest descriptions realised 6s. 2d. per 8 lb., but these were very scarce, and our quotations more fairly represent the average. There were a few more sheep; there was, however, a demand for them, but late rates were not so freely given. Trade was dull for calves. Quotations:—Beasts, 4s. 6d. to 5s. 2d., and 5s. 6d. to 6s.; calves, 4s. 6d. to 6s.; sheep, 5s. 4d. to 5s. 8s., and 6s. 4d. to 7s.; pigs, 4s. to 5s.—Thursday's cattle trade was much as above reported. For fine breeds, both of beasts and sheep, the market was fairly steady, and Monday's prices were well supported, otherwise the tone was rather quiet, and quotations remain about the same. Calves were in moderate supply.

HAY.

The Whitechapel report for Tuesday states that trade was dull at barely previous quotations. The supply was fair. Prime Clover, 100s. to 137s.; inferior, 85s. to 95s.; prime meadow hay, 90s. to 102s.; inferior, 75s. to 85s.; and straw, 44s. to 54s. per load.—With only a moderate supply at market, trade on Thursday ruled rather quiet at the above prices.—Cumberland Market quotations:—Superior meadow hay, 105s. to 112s.; inferior, 80s. to 92s.; superior Clover, 132s. to 140s.; inferior, 100s. to 110s.; and straw, 54s. to 58s. per load.

POTATOS.

The Borough and Spitalfields markets reports note that good Potatos, of which the supply is not overplentiful, meet with a steady demand at previous rates. Inferior Potatos remain dull. Kent Regents, 160s. to 190s.; Essex do., 110s. to 160s.; rocks, 110s. to 125s.; Victorias, 160s. to 180s.; flukes, 160s. to 170s.; and kidneys, 120s. to 140s. per ton.—The imports into London last week consisted of 83,991 bags from Hamburg, 20,483 bags 215 tons Antwerp, 7103 Bremen, 6106 Stettin, 4063 Ghent, 1358 Harlingen, 1801 Dunkirk, 1213 Rotterdam, 3470 Dantzic, 531 Brussels, 241 Boulogne, 134 Chante, and 115 tons Rouen.

COALS.

At market both on Monday and Wednesday there was a good demand for house coals. The last quotations to hand are:—Walls End—Hetton, 20s.; Hetton Lyons, 17s. 9d.; Lambton, 19s. 6d.; Wear, 17s. 6d.; Tunstall, 17s. 9d.; East Hartlepool, 19s. 9d.

Estd. 1844.

- 12 Scilla amœna
- 2 Lilium caudidum
- 12 Spanish Iris
- 9 Herbaceous and Alpine Plants,

WITH FULL CULTURAL DIRECTIONS.

Case, Packing, and Carriage Free to any Railway Station in England and Wales.
Other Collections, for Greenhouses or Conservatory, &c., 12s. 6d., 21s., 42s., 63s., and 84s. each.

From Mr. H. BENNETT, Belle Vue Crescent, Clifton, Bristol. March 10, 1877.

"I am glad to tell you that the Hyacinths, Tulips, and Crocus I had in the Autumn have given entire satisfaction: the flowers are splendid."

From R. PRYNCE, Esq., Bathgate, N.B. February 7, 1877.

"The Bulbs received from you in the Autumn have been particularly fine; some of the Hyacinths and Tulips now in bloom are large and beautiful, and have far exceeded any that I have had before."

We can supply Foundation Plates—which form Ash-pit—and Smokestacks, if wanted, thereby doing away with the necessity for even a single brick in their erection.

	A	B	C	D	E
	s. d.	s. d.	s. d.	s. d.	s. d.
Foundation Plate ..	35 0	45 0	60 0	75 0	90 0
Smokestack, Damper, and Scot-Door ..	30 0	30 0	40 0	40 0	40 0
Furnace and Ash-Pit, Frame and Doors; also Furnace Bars, Bearers, Dumb-Plate, &c. ..	30 0	40 0	50 0	60 0	70 0

Foundation Plates are arranged to heat the air before it is sent into the ash-pit at back, and furnace-doors to heat the air before its admission into the furnace; furnishing in fact two "hot-air" blasts to the furnace; the admission of large volumes of cold air being most injurious to the economical working of the furnace.

In preparation an entirely NEW SERIES of SEVENTY BOILERS, embracing a large variety suitable for small places, &c., and all specially adapted for low situations where shallow boilers are a necessity. Particulars on application.

WM. WRIGHT & CO.,
AIRDRIE, N.B.

DWARF ROSES, on the cultivated Seedling Brier, of the leading Exhibition varieties, 9s. per dozen, package free. Cash to accompany order.
JOHN HOUSE, F.R.H.S., Eastgate Nurseries, Peterborough.

JOHN LUFF, St. Helen's Nursery, Hastings, offers as under, at low prices for Cash, to clear ground for other Stock: the plants have been twice and thrice transplanted, and are growing on high and exposed ground, and will move well. Samples at same rates:—
LIMES, 4 to 6 feet, 4s. per dozen; 6 to 8 feet, 9s. per dozen.
ELMS, 4 to 6, 40s. per 100; 6 to 8 feet, 50s. per 100.
SYCAMORE, 5 to 7 feet, 30s. per 100; 8 to 9 feet, 50s. per 100.
HORNBEAM, 4 to 6 feet, 10s. per 100.
NORWAY MAPLE, 4 to 6 feet, 15s. per 100; 6 to 9 feet, 30s. per 100.
FIR, Silver, 3 to 4 feet, 3s. per dozen; 4 to 5 feet, 6s. per dozen; 5 to 6 feet, 9s. per dozen.
Spruce, 3 to 4 feet, 6s. per dozen; 4 to 5 feet, 9s. per dozen; 5 to 6 feet, 12s. per dozen.
Scotch, 2 to 4 feet, 12s. per 100; 4 to 6 feet, 15s. per 100; 6 to 8 feet, 25s. per 100.
ARBOR-VITÆ, American, 2 to 3 feet, 4s. per dozen; 3 to 4 feet, 6s. per dozen.
THUJA GIGANTEA, 3 to 4 feet, 6s. per dozen; 4 to 5 feet, 9s. per dozen.
YEW, English, 2 to 3 feet, 8s. per dozen; 3 to 4 feet, 12s. per dozen; 4 to 5 feet, 18s. per dozen.
ASH, 2 to 4 feet, 25s. per 100.
HOLLIES, Green, 1½ to 2½ feet, 5s. per dozen; 2½ to 3 feet, 6s. per dozen.
ASPARAGUS, 20,000 Grayson's Giant, 2-yr., 2s. per 100.
20,000 Grayson's Giant, 3-yr., 3s. 6d. per 100.

AMIES' CHEMICAL MANURE.
 USED BY THE ROYAL HORTICULTURAL AND BOTANIC SOCIETIES.

This Manure, after six years' trial, is unapproached in its results by any other manure. It is suitable for all soils, and permanently improves the fertility of even the poorest. It provides the necessary foods for plants, creates a vigorous growth without over-stimulating, and it increases the produce. It is a powerful insecticide. It has been used with perfect success on

FLOWERS, SHRUBS, VEGETABLES, FRUITS, GRASS, VINES.
 PREPARED IN A FINE, DRY, INODOUS POWDER.
 Price, £12 per Ton; 16s. per Cwt.; and in Canisters, 1s., 2s. and 4s. each.
 Trial Orders of the Manure are invited, to be used in comparison with other Manures.

Write for Further Particulars to
AMIES' CHEMICAL MANURE CO. (LIMITED),
 79, MARK LANE, LONDON, E.C.

SIMPSON'S RED SPIDER, THrips, &c., ANTI-DOSE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d. Supplied to Seedsmen and Chemists. Strongly recommended in the *Gardener*, and by many first-class Gardeners.
 Prepared by **JOHN KILNER,** Wortley, near Sheffield.

GISHURST COMPOUND.— Used by many of the leading Gardeners since 1850, against Red Spider, Mildew, Thrips, Greenfly, and other Blight in solutions of from 1 to 2 ounces to the gallon of soft water, and of from 4 to 16 ounces as a winter dressing for Vines and Fruit Trees. Has obtained many preparations intended to supersede it. Sold Retail by Seedsmen, in Boxes, 1s., 3s., and 10s. 6d. Wholesale by **PRICE'S PATENT CANDLE COMPANY (Limited).**

PUBLISHING OFFICE and OFFICE for ADVERTISEMENTS, 41, Wellington Street, Covent Garden, London, W.C.

CRITCHLEY'S PATENT HEAT REGULATOR,

AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe or Supply of Water from Boiler. C, D, Pipes for Circulating Hot Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.

The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—

Berkeley Castle, April 13, 1875.

"Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes.

"I am, Gentlemen, yours truly, "R. H. CRONK, "Gardener to the Right Hon. Lord Fitzhardinge."

Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the Kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

Messrs. CRITCHLEY & CO., Horticultural Engineers and Builders, GROSVENOR WORKS, CHELTENHAM.

STOVES, Terra-Cotta! Portable! For Coall ROBERTS'S PATENT.

Healthy Heat twenty-four hours or longer for about 1d., without attention. For Heating Greenhouses, or almost any purpose. Prospectus and authenticated Testimonials sent. In use daily at Patentee's, THOMAS ROBERTS, 112, Victoria Street, Westminster, S.W.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved.

Copy of a Testimonial.

"Messrs. SILVESTER. "Royal Exotic Nursery, King's Road, Chelsea, S.W.—Aug. 8, 1877.

"GENTLEMEN,—In reply to your enquiry as to our opinion of your Stevens' Trentham Boilers, we do not hesitate to pronounce them to be by far the best Boilers we have ever used. Our establishment is a very large one, and we have tested most of the various descriptions of Boilers which have been brought out from time to time. We originally commenced with one Trentham Boiler, and we have now *hundreds* of various sizes at work. "For certainty of action, economy in fuel, and freedom from breakdown, we have never had a Boiler at all equal to the Stevens' Riveted Trentham Boilers supplied by you, and we have never felt so little anxiety in connection with our hot-houses during the cold winter months as we do now.

"We are not in the habit of giving testimonials, but we think this may fairly be an exception to our rule, as the matter is one of such importance to the Gardening Public generally, and our experience has led us to form a very decided opinion.

"We are, Gentlemen, yours faithfully,

"JAMES VEITCH AND SONS."

For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER,

HOT-WATER ENGINEERS, &c., &c., Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

Silver Medal, 1874.

THE TERMINAL SADDLE BOILER.—First-class Certificate, 1867; Highly Commended, 1873; and First-class Certificate, 1875.

"This Boiler possesses the rare merit of sucking all the heat from the fire."—*Gardener's Magazine*, p. 254. "I have no doubt the Best Boiler, that will burn any kind of fuel, is the Terminal Saddle."—*Journal of Horticulture*, p. 327. "For moderate cost and real efficiency the Terminal Saddle is one of the very best."—*The Gardener*, p. 95. Prospectus post free.

T. JONES, Temple Street, Manchester.

SILVER MEDAL

AWARDED AT

Birmingham Meeting, Royal Agricultural Society, 1876.

1876.

HIGHEST HONOR AT THE Centennial Exhibition, Philadelphia.

Specially adapted for Pumping in Gentlemen's Houses and Grounds. No Labor Required.

HAYWARD TYLER & Co., 84, WHITECROSS STREET, LONDON.

Wages 4s per week with cottage and conveniences adjoining gardens.—G. Pearson & Son, 35, Bishopsgate Within, London, E.C.

WANTED, within the suburbs of Brighton, a practical and good WORKING GARDENER and his WIFE, without encumbrance; the Wife to undertake the Laundry. Establishment is only small. A comfortable and well-built cottage provided.—For particulars, J. T. Eastern Villa, Havant.

WANTED, IMMEDIATELY, as UNDER GARDENER, where four are kept, a strong young Man, used to Kitchen Garden Work. Men from Nurseries not accepted. Character required from last employers.—ALPHA, Post-office, Roehampton, S.W.

To Nurserymen. WANTED, a thoroughly industrious and intelligent Man, as PROPAGATOR of Ericas and other Hard-wooded Greenhouse Plants, Rhododendrons, Roses, Clematis, &c., on an extensive scale.—State experience, wages expected, &c., to N. B., Gardener's Chronicle Office, W.C.

PROTHEROE and MORRIS are in WANT of a KNIFEMAN, who understands Layering, for their Nursery at Wanstead Flats.—American Nurseries, Leytonstone, E.

Nursery Foreman. WANTED, IMMEDIATELY, a steady, active MAN, who has a thorough practical knowledge of Conifers, Fruit Trees, Shrubs, Greenhouse and Herbaceous Plants, &c.; must be a good Propagator, able to Draw Plans, assist in Correspondence, and take an occasional Journey if necessary.—Apply, stating age, experience, and wages expected, to THOMAS KENNEDY AND CO., Seedsmen and Nurserymen, Dumfries.

WANTED, as NURSERY FOREMAN and SALESMAN (Out-of-door), a Man perfectly competent to act in both capacities, and who can be highly recommended for honesty and sobriety. To such, liberal wages and a comfortable situation will be found by applying to D. H. HIGGINS, The Old-Established Nurseries, Clonmel, Ireland.

WANTED, a strong, steady Young Man to attend to the Fires, Paint and Glaze, and make himself generally useful. None need apply whose character will not bear the strictest investigation. Wages 25s. per week.—JOHN WILLS, Royal Exotic Nursery, South Kensington, S.W.

WANTED, a steady, married MAN; must understand Furnishing, Box Filling, and Nursery Work.—Apply, between 7 and 8 P.M., to G. D. TAVINER, Coburg Place, Bayswater Road, W.

WANTED, a HEAD SHOPMAN and occasional TRAVELLER, in a Wholesale Seed Establishment; must be a good Correspondent.—Apply, by letter, stating age, experience, and salary required, addressed A. B. C., Gardener's Chronicle Office, W.C.

Second Shopman. WANTED, an energetic Young Man in above capacity; must have a good general knowledge of the Seed and Nursery business, and be quick and obliging. None need apply whose character will not bear the strictest investigation. State age, references, wages expected, &c.—DANIELS BROS., The Royal Norfolk Seed Establishment, Norwich.

WANTED, IMMEDIATELY, a respectable Man, as CURATOR and REGISTRAR for Egremont Cemetery. Wages, 24s. per week, and free house.—Applications, with references, may be sent to the CLERK to the Burial Board, Egremont, Carnforth, on or before Dec. 1.

WANT PLACES.

E. P. DIXON can at present recommend several excellent GARDENERS, and will be pleased to answer any enquiries from Ladies and Gentlemen requiring such.—The Yorkshire Seed Establishment, Hull.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

E. G. HENDERSON AND SON have many excellent GARDENERS with approved testimonials for ability now waiting in their Nurseries for re-engagement.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pine-apple Nursery, Maida Vale, London, W.

GARDENER (HEAD).—Age 26, married (two young children). Thoroughly understands Hot-houses, Fruit, Flower and Kitchen Gardening.—H. KENTISH, Cliffe Rectory, Rochester.

GARDENER (HEAD).—Age 36, married; understands the profession in all its branches. Eight years' good character from last situation.—G. F., Rose Cottage, Bracebridge, Lincoln.

GARDENER (HEAD), where one or two others are kept.—Eleven years' experience in all branches of Gardening in some of the best places. First-class character.—For particulars apply to Mr. J. SHRIVES, Royal Pavilion Gardens, Brighton.

GARDENER (HEAD, WORKING).—Age 42 married, no family; has a thorough practical knowledge of the profession in all its branches, including Land and Stock.—J. P., 104, High Road, Lewisham, S.E.

GARDENER (HEAD, WORKING).—Age 26, married; thoroughly understands Stove and Greenhouse Plants, Vines, Peaches, Melons, Cucumbers, Flower and Kitchen Gardening. Good reference.—A. B., Hatching Green, St. Albans, Herts.

GARDENER (HEAD, WORKING).—Age 30; thoroughly experienced in the Cultivation of Orchids, Stove and Greenhouse Plants, Pines, Vines, Peaches, Melons, Flower, Fruit, and Kitchen Gardening. Excellent character and reference.—H. T., 2, High Street, Somerstown, Chichester.

GARDENER (HEAD, WORKING), to any Lady or Gentleman requiring the services of a thoroughly practical Man in every department of Horticulture.—Age 30, single. First-class testimonials.—Address, with particulars, A. P., Rev. J. Savage, Rowland's Castle, Havant, Hant.

GARDENER (HEAD, WORKING, where another is kept, or good SINGLE-HANDED).—Age 39; understands Forcing Vines, Stove and Greenhouse Plants, Flower and Kitchen Gardening and Orchard-house. Wife could take a small Laundry. Good reference. Country preferred.—J. TAYLOR, Thong, near Gravesend.

GARDENER (FIRST-CLASS).—Age 32; thoroughly competent, having had good practice from early youth in all that appertains to the successful Culture of choice Flowers, Fruits, and Esculents, with the general Management of a Garden Establishment on any extent. Is thoroughly steady, energetic, and not afraid of work.—D. KNIGHT, 24, Orford Street, Wavertree, Liverpool.

GARDENER (HEAD), or GARDENER and BAILIFF.—Age 34, married; eighteen years' experience in first-class places, five as Head Gardener. Unexceptionable character and testimonials from last and previous situations.—VERTIS, 436, Wandsworth Road, S.W.

GARDENER (HEAD, WORKING, or SINGLE-HANDED).—Age 32, married; thoroughly understands Pines, Vines, Stove, Cucumbers, Melons, Kitchen Garden, &c.; six years' good character. First-class references.—A. E., 15, Cross Street, West Ham Lane, Stratford, E.

GARDENER (HEAD, or good SINGLE-HANDED).—Married, no family; sixteen years' experience in all branches. Good character from last situation. Please state particulars.—J. B., 13, Whately Road, Peage, S.E.

GARDENER.—JOHN COWAN, The Vineyard, Garston, near Liverpool, would be glad to recommend to any Nobleman or Gentleman requiring a first-class Gardener a Man in the prime of life, who thoroughly understands the profession in all its branches, having had many years' experience in some of the best places in England and Scotland.

GARDENER.—GEORGE LEGG, late Gardener to S. Ralli, Esq., Clevedon House, Clapham Park, London, S.W., is still disengaged, and respectfully offers his services to any Nobleman, Lady, or Gentleman requiring a persevering and successful Gardener. The position he has won as an Exhibitor of Plants at the Great Metropolitan Shows, and the condition of Mr. Ralli's garden (which has been inspected by visitors from all parts of the Kingdom), afford the best evidence of his competency.—G. LEGG, 1, Park Villas, Kenilford Road, Balham, S.W.

GARDENER, where help is given.—Age 25, single; good experience in Early and Late Forcing, Cucumbers, Melons, Grapes, and Flower and Kitchen Gardening. Good character.—T. C., Mr. Southern, Shardlow, Derby.

GARDENER (KITCHEN, UNDER, or SINGLE-HANDED).—Age 23, single; no objection to a Pony. Good character.—A. B. C., Bridgers, Paddock Wood, Kent.

GARDENER (UNDER).—Age 19; willing to make himself useful. Good character.—F. B., The Willows, Great Malvern.

GARDENER (UNDER), or IMPROVER.—Has had five years' experience.—WILLIAM BOX, Turville Heath, Henley-on-Thames.

JOURNEYMAN, or UNDER GARDENER, in a Gentleman's Establishment.—Young; eight years' experience in all branches. Good references.—Apply, stating wages, &c., to J. G., 15, St. Margaret's, near Hemel Hempstead, Herts.

FOREMAN, in a good Establishment.—Age 25. Good character.—D. M. R., May Cottage, Farm Avenue, Streatham, S.W.

MANAGER, FOREMAN, or FOREMAN and PROPAGATOR.—Practically acquainted with the profession in all its branches, including the Growth of Plants and Flowers for Market. First-class references.—ALPHA, Messrs. Pengilly & Pool, 59, Queen Victoria Street, E.C.

To Nurserymen. FOREMAN (GENERAL), or SALESMAN.—Twelve and a half years' experience in general Nursery Work; has a thorough knowledge of Stove and Greenhouse Plants. Six and a half years with Messrs. James Veitch & Sons, and for the past four years Foreman and Salesman in the Stove Plant Department.—J. B., Messrs. James Veitch & Sons, Chelsea.

APPRENTICE, in a First-rate Garden, for three years.—Age 17. Will pay a premium of £5 a year.—WILLIAM EARL, Gardener, Feverel Court, Aylesbury, Bucks.

Seed Trade. SHOPMAN.—Age 24; eight years' general experience. Best of references.—ALPHA, Mr. Parsons, Seedsman, Nicholas Street, Bristol.

TO WHOLESALE NURSERYMEN and SEEDSMEN.—The Advertiser desires to meet with an engagement to take Periodical Journeys for a good House; has a thorough knowledge of both trades.—A. B. C., Post-office, Chester.

BOOK-KEEPER, or CLERK, in a Nursery or Seed Business.—Age 32. First-class references.—K. W., 2, Francis Street, Chester.

ASSISTANT, in a Fruit or Seed Business.—Age 25; respectable.—S. E. H., Holly Cottage, Reddish, near Stockport.

Seed Trade. COUNTER-HAND.—Age 21; seven years' experience in Retail Houses. Satisfactory references.—G. W., 36, Cochrane Street, St. John's Wood, N.

TO LAND AGENTS and STEWARDS.—A Land Surveyor, practising in London, is desirous of placing a Son with a Gentleman of Position, where a knowledge of Farming, Soils, Agricultural Customs, and the General Management of Estates could be acquired.—X., Mr. Ryde, 29, Great George Street, Westminster, S.W.

KINAHAN'S LL WHISKY. Universally recommended by the Medical Profession. A pure old spirit, mild, mellow, delicious, and most wholesome. Dr. Hassall says, "The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality."—Wholesale: 20, Great Titchfield Street, London, W.

GRATEFUL—COMFORTING.

E P P S ' S (BREAKFAST) C O C C O A .

JAMES EPPS & CO., HOMEOPATHIC CHEMISTS.

DINNEFORD'S FLUID MAGNESIA. The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants. DINNEFORD AND CO., 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS.—Pure Blood.—When the blood is pure, its circulation perfect, and the nerves in good order, we are well. These Pills possess a marvellous power in securing these great secrets of health by purifying, regulating, and strengthening fluids and solids. Holloway's Pills can be confidently recommended to all persons suffering from Disordered Digestion, or Worried by Nervous Fancies, or Neuralgic Pains. They correct acidity and heartburn, dispel sick headache, quicken the action of the liver, and act as alteratives and gentle aperients. The weak and delicate may take them without fear. Holloway's Pills are eminently serviceable to invalids of irritable constitution, as they raise the action of every organ to its natural standard, and universally exercise a calming and sedative influence.

BULBS, CAMELLIA STOCKS, CARNATIONS and

PICOTEES, FRUIT and FOREST TREES, SHRUBS, &c.

CATALOGUES of which may be obtained on application.

BEAUTY OF HEBRON POTATO.—This

new American sort is now offered for the first time.

This valuable Potato originated in 1874 from seed bulbs of the

Chili Red. The vines and leaves strongly resemble those of the

Early Rose, only more vigorous. The plants appear above-

ground very shortly after planting, and from that time continue

to grow with great rapidity, outstripping all other varieties in

length of growth and luxuriance of foliage. On this account it

will be understood they withstand better the ravages of the

Colorado Potato Beetle than any other Potato yet brought

before the public. The tubers, shaped like those of the

Early Rose, are very smooth, slightly tinged with pink

around the eyes, but attain a pure white colour during the

winter. Their yield is really enormous. The tubers lying

closely together in the hills, the labour of digging them is but

slight. In point of earliness it may be ranked as ripening at

least twelve days earlier than the Snowflake, and no less than

three or four days ahead of the Early Rose. For culinary

purposes its mealy qualities and richness and delicacy of

flavour give it a precedence before all other varieties. Contrary

to what is usually the case in all large specimens of Potatoes the

Beauty of Hebron almost invariably prove sound and solid to

the core.

May be obtained of the principal Seedsmen of England.

J. M. THORBURN and CO., 15, John Street, New York,

U.S.A.

 Seed Growing Establishment, Wisbech.

MESSRS. CHARLES LEE AND SON, Royal Vineyard Nursery, Hammersmith, London, W., have much pleasure to offer the following very beautiful and interesting NEW FRUITS, now offered by them for the first time:—

RUSSIAN TRANSPARENT APPLE.—In the Journal of Horticulture, December 21, 1876, "Lincolnshire," describes this valuable Apple as giving a "never-failing crop," and as being "a rent-paying tree" for cottage gardens. Mr. BEULAH, an experienced Lincolnshire Orchardist, confirmed this evidence of the usefulness and profitableness of this much neglected but desirable Apple. A tree that bears a never-failing crop, of excellent quality, as stated below by Dr. Hogg, must be as near perfection as possible, and a desideratum that cannot fail to be appreciated by Orchardists in general. The Russian Transparent Apple was brought from Moscow during Napoleon's campaign in Russia, by General Boucheret, who, noticing its hardiness and free growth, and believing it would be suitable for English gardens, brought a quantity of grafts to his home in North Lincolnshire, round which it became and has remained up to this time localised; and now, through the kindness of Mr. Beulah, we have been enabled to purchase all the available grafts from the original stock.

The following is from Dr. Hogg's description:—"Fruit large, roundish, somewhat oblate, narrowing towards the crown, where it terminates in several prominent ridges, flat at base; skin smooth and shining, grass green, strewed with large russet spots. Eye closed. Flesh very tender and juicy, with a pleasant sub-acid flavour, and a peculiar and agreeable aroma. I am convinced that this is one of the most valuable culinary Apples in cultivation, and is worthy of more than local fame."

Messrs. Charles Lee & Son have much confidence in introducing this desirable and profitable Apple to more extended cultivation. Strong Maiden Plants now ready, price 7s. 6d. each.

HENSON'S SEEDLING GOOSEBERRY.—This excellent variety was figured in the Florist and Pomologist for May, 1874, a First-Class Certificate having been awarded to it by the Fruit Committee of the Royal Horticultural Society in 1873. It was described as "a new and distinct variety of exceedingly good quality, of the hairy red section, and a good dessert fruit of medium size."

Messrs. Charles Lee & Son having purchased the entire stock of this valuable Gooseberry they are now prepared to distribute it to the Public. Price per Plant, 3s. 6d. The usual discount to the Trade.

PLANTING SEASON.

FOR IMMEDIATE EFFECT.

JAMES IVERY & SON

Beg to offer well grown stuff of the following, at very low prices, being overstocked with them:—

- LAURELS, fine bushy plants, 6, 7, and 8 feet.
YEWS, fine bushy plants, 6, 8, and 10 feet.
GREEN HOLLIES, fine bushy plants, 5, 7, and 9 feet.
TREE BOX, fine bushy plants, 5 to 6 feet.
RISH YEW, fine bushy plants, 6, 7, and 9 feet.
UPRESSUS LAWSONIANA, fine bushy plants, 10 to 12 feet.
ARCH FIR, 8 to 10 feet.
PINUS AUSTRIACA, 6 to 10 feet.
STROBUS (Weymouth Pine), 6 to 10 feet.
ARAUCARIA IMBRICATA, splendid specimens, 8, 10, and 20 feet.
PINUS EXCELSA, splendid specimens, 10, 15, and 20 feet.
SPRUCE FIR, splendid specimens, 8, 10, and 12 feet.
SILVER FIR, splendid specimens, 10 to 12 feet.
SYCAMORE, 10 to 15 feet.
BIRCH, 10 to 12 feet.
AILANTUS GLANDULOSA, 8 to 10 feet.
POPLARS, in variety, 6, 8, and 9 feet.
LIMES, very fine, straight stems, 10, 15, and 20 feet.
NUTS, various, large quantities, including many of Webb's new kinds, 4, 6, and 8 feet.
WALNUTS, standards, fine heads, stems 5 to 6 feet.
MULBERRIES, Standards, fine heads, stems 5 to 6 feet; probably the largest and best stock in the kingdom.

Also a large collection of GENERAL NURSERY STOCK too numerous to mention.

Prices on application at THE NURSERIES, DORKING, SURREY.

SPRING FLOWERING PLANTS.

- ANEMONE FULGENS, strong plants, established in pots, 12 each, 10s. per dozen, 75s. per 100. This is the most dazzling scarlet, and commences to open its flowers in January and continues until May. Most invaluable for the spring garden, and also for cutting, as it opens its flowers just as well under artificial as light.
CARDAMINE PRATENSIS, fl. pl. Double Lilac, flowers most profuse, first-rate spring flower, 25s. per 100.
PRIMROSE, Double Crimson (true), 18s. per dozen, 140s. per 100.
Double Crimson Purple, fine variety, often throwing up its flowers in scapes, and continuing long in bloom, 6s. per dozen, 45s. per 100.
Double Yellow, 4s. per dozen, 25s. per 100.
Double Lilac, 3s. per dozen, 16s. per 100.
Double White, 3s. per dozen, 20s. per 100.
Single Yellow, flowering in scapes, most continuous, 6s. per dozen, 40s. per 100.
POLYANTHUS, strong fine strain, 3s. per dozen, 12s. 6d. per 100.
PHLOX, verna, 4s. per dozen, 20s. per 100.
setacea, 4s. per dozen, 20s. per 100.
WALLFLOWERS, Single, Harbinger, Tom Thumb, yellow and early dark brown, 1s. 6d. per dozen, 8s. per 100.
Double German, eight distinct colours, separate, very strong, 1s. 6d. per dozen, 8s. per 100.
Double, Golden Drop (pots), 3s. 6d. per doz., 25s. per 100.
Double, black and striped (pots), 4s. per dozen.
DAISY, Double Crown, very large, 3s. 6d. per 100.
Snowball, fine, 3s. 6d. per 100.
Crimson, 5s. per 100.
Aucubifolia, 10s. per 100.
Small White French and Carmine French, two very pretty sorts, 7s. 6d. per 100.
Cœrulea (Blue Daisy), 4s. per dozen.
IRIS, pumila, 3s. per dozen.
MYOSOTIS, rupicola (pots), grows 3 inches high, 2 gem, 6s. per dozen.
RODGER, McCLELLAND AND CO., Nurserymen, &c., Newry.

AVENUE TREES.

PLANE TREES.—Several thousands of the true Platanus occidentalis, from 10 to 20 feet high, straight stemmed, stout, and splendidly rooted.

LIMES, 10 to 20 feet high.

POPLAR, canadensis nova, 12 to 20 feet high.

These Trees have been grown expressly for Street and Avenue Planting.

They are to be seen growing at Knap Hill, and are, without question, the finest stock of their kinds to be found in any Nursery in Europe.

ANTHONY WATERER, KNAP HILL, WOKING, SURREY.

DWARF ROSES ON THE CULTIVATED SEEDLING BRIER.

The only establishment where this stock is used exclusively for Roses.

CATALOGUES ON APPLICATION.

GEORGE PRINCE, 14, MARKET STREET, OXFORD.

VINES, FRUIT TREES, EVERGREENS, SHRUBS, &c.

CATALOGUES Post-free.

PLANTING and FRUITING CANES, well ripened, with good fibrous roots, of the undermentioned, 2s., 2s. 6d., 3s. 6d., 5s., and 7s. 6d. each:—Barbarossa, Pearson's Golden Queen, Dr. Hogg's Royal Muscadine, Black Hamburg, Black Alicante, Madresfield Court, Lady Downe's, Gros Colman, Foster's Seedling, Buckland's Sweetwater, Muscat of Alexandria, West's St. Peter's, Yenn's Black Muscat.

APPLES and PEARS, fine Pyramid, 9s. to 18s. per dozen.

PEARS, Dwarf-trained, exceedingly fine trees, 30s. per dozen.

SPRING BEDDING PLANTS, BULBS, FLORISTS' FLOWERS, HERBACEOUS PLANTS, &c.—See Advertisements in Gardeners' Chronicle from October 20 to November 24, for List and Prices.

CATALOGUES of above, Roses, Fruit Trees, &c., post-free.

WM. CLIBRAN & SON, OLDFIELD NURSERY, ALTRINCHAM.

MYROBALAN, or CHERRY PLUM, is the best staff for Mending Old Fences or Making New Ones. It grows vigorously in the poorest soils, even where Whitethorn will hardly exist, and bears clipping like Whitethorn. Its stiff hard branches, and dangerous spines or thorns, effectually prevent cattle or evil-disposed persons from getting through Fences made of it. Plant from four to six in a yard. Sizes and prices on application to EWING AND COMPANY, The Royal Norfolk Nurseries, Eaton, near Norwich.

STOTT'S MONARCH RHUBARB.

The stems grow to an enormous size, and are of a fine Gooseberry flavour. From the Cranston "Weekly Globe."—"Shirley Hibberd says that any one who wants Rhubarb that makes leaves as big as a dining table, or stems as thick as a Cedar Tree, that rise as high as a tall human dwarf, should order Stott's Monarch at once. After being at sea for three years as to the whereabouts of this wonderful Rhubarb, he has at last discovered that it is to be obtained from Stuart & Mein, Kelso." Roots 1s. 6d. each.

STUART, MEIN AND ALLAN, Nurserymen and Seedsmen, Kelso.

Queen of Lilies, Lilium auratum.

As this year's shipments will be shortly arriving from Japan, WILLIAM GORDON begs to call attention to the following low prices:—Size 3, No. 1, 6d.; No. 2, 1s.; No. 3, 1s. 6d.; No. 4, 2s. each. Sampling orders are supplied only in the following quantities, and are carefully packed in tin boxes to contain only the following number of bulbs, the prices quoted including carriage to any part of the United Kingdom:—2 bulbs, 6d. extra; 4 bulbs, 1s. 6d.; 8 bulbs, 2s.; 12 bulbs, 2s. 6d., added to the foregoing prices. Quantities of 18 bulbs and over package and carriage free, less 10 per cent. discount. LILY LIST on application. WILLIAM GORDON, Lily, Bulb, and Plant Importer, 10, Cullum Street, London, E.C.

JOHN LUFF, St. Helen's Nursery,

Hastings, offers as under, at low prices for Cash, to clear ground for other Stock; the plants have been twice and thrice transplanted, and are growing on high and exposed ground, and will move well. Samples at same rates:—

- LIMES, 4 to 6 feet, 4s. per dozen; 6 to 8 feet, 9s. per dozen.
ELMS, 4 to 6, 40s. per 100; 6 to 8 feet, 50s. per 100.
SYCAMORE, 5 to 7 feet, 30s. per 100; 8 to 9 feet, 50s. per 100.
HORNBEAM, 4 to 6 feet, 12s. per 100.
NORWAY MAPLE, 4 to 6 feet, 15s. per 100; 6 to 9 feet, 30s. per 100.
FIR, Silver, 3 to 4 feet, 3s. per dozen; 4 to 5 feet, 6s. per dozen; 5 to 6 feet, 9s. per dozen.
Spruce, 3 to 4 feet, 6s. per dozen; 4 to 5 feet, 9s. per dozen; 5 to 6 feet, 12s. per dozen.
Scotch, 2 to 4 feet, 12s. per 100; 4 to 6 feet, 15s. per 100; 6 to 8 feet, 25s. per 100.
ARBOR-VITAE, American, 2 to 3 feet, 4s. per dozen; 3 to 4 feet, 6s. per dozen.
THUJA GIGANTEA, 3 to 4 feet, 6s. per dozen; 4 to 5 feet, 9s. per dozen.
YEWS, English, 2 to 3 feet, 8s. per dozen; 3 to 4 feet, 12s. per dozen; 4 to 5 feet, 18s. per dozen.
ASH, 2 to 4 feet, 25s. per 1000.
HOLLIES, Green, 1 1/2 to 2 1/2 feet, 5s. per dozen; 2 1/2 to 3 feet, 6s. per dozen.

 W. EALL AND CO., The Nurseries, Bedford Road, Northampton.

THE NEW WEEPING WELLINGTONIA.

WELLINGTONIA GIGANTEA PENDULA.

This excellent novelty is very distinct from *W. gigantea* through its branches being pendant instead of erect; it might, indeed, be called the Weeping Wellingtonia. This habit gives it the appearance of a column, its numerous branches being so evenly placed. It is a tree which will in time become indispensable for Lawns both large and small, as its drooping branches do not take up much space.

Fine Specimens, 3 to 4 feet, 65s. to 75s. each.

Plants 6 to 8 inches high, 25s.; 8 to 12 inches high, 27s. 6d.; 12 to 17 inches high, 35s.; 17 to 21 inches high, 40s. each.

THE QUEEN'S SEEDSMAN,
 HIGH HOLBORN LONDON, W.C.

COCOA-NUT FIBRE REFUSE,
 Reduced price:—In 4 bushel bags, at 1s. 3d. (not less than 5 bags), or truck load for 30s. (truck load delivered free to rail in London). A remittance to accompany all orders.
 J. STEVENS AND CO., Greyhound Yard, and 134, High Street, Battersea, S.W.

PEAT.—For Sale, a quantity of Brown Fibrous and Black. For price, &c., apply to Mr. G. HILLS, Tekels Estate, Frimley, Farnborough, Hants.

PEAT SOIL, PEAT SOIL.—Brown Fibrous, good quality, for Orchids, Pot Plants, Ferns, &c., 6s. 6d. per truck. Black, good quality, for American Plants, Rhododendrons, Azaleas, Heaths, &c., 17s. per ton, or 6-ton truck for 44 10s. Delivered on rail at Blackwater, South-Eastern Railway, or Farnborough, South-Western Railway, by the truckload. Cash with order.
 HOLDER AND SON, Crown Nurseries, Reading.

Fibrous Peat for Orchids, &c.
BROWN FIBROUS PEAT, best quality for Orchids, Stove Plants, &c., 6s. 6d. per truck.
BLACK FIBROUS PEAT, for Rhododendrons, Azaleas, Heaths, American Plant Beds, 17s. per ton.
 Delivered on rail at Blackwater, S. E. R., or Farnborough, S. W. R., by the truck-load. Sample sack, 5s. 6d. each.
 Fresh SPHAGNUM, 10s. 6d. per sack.
 WALKER AND CO., Farnborough Station, Hants.

NOVELTIES FOR 1878.

JAMES VEITCH & SONS

DESIRE TO DIRECT ATTENTION TO THE FOLLOWING NEW AND CHOICE SEEDS:—

AQUILEGIA CALIFORNICA HYBRIDA.

NEW PEA, "HARBINGER" (Laxton).

The following description is taken from the Royal Horticultural Society's report of the great trial of Peas at Chiswick, in 1872:—

"A cross between Dillistone's Early and Alpha. The plant has the habit of Dillistone's Early. Stem $2\frac{1}{2}$ to 3 feet, simple, producing from seven to eight pods singly. The pods are small, rounded in form, slightly curved, very tightly filled, of a light green colour, and contain about six fair-sized Peas of a fine colour and good flavour. Ripe seed

small, round, blue. Sown February 23, first flower opened May 9, was in full flower May 15, slats appeared May 21, fit for use June 26. The earliest Pea in the collection, being three days earlier than Dillistone's Early, and six days earlier than Sangster's No. 1. Received a First-class Certificate."

It is also somewhat similarly described in Hogg's *Year Book* for 1873, page 87.

Price, 3s. 6d. per Half-pint Packet.

VEITCH'S SELF-PROTECTING AUTUMN BROCCOLI.

A very valuable Broccoli for autumn and early winter use. The plant is of robust but upright growth, and the heads, which are beautifully white, firm and compact, are thoroughly protected by the foliage, and remain a long time fit for use. It will be found extremely valuable as a succession to our Autumn Giant Cauliflower, which has met with so much approval, and is now an established favourite in all gardens.

Price, 1s. 6d. per Packet.

CAULIFLOWER, "VEITCH'S AUTUMN GIANT."

This extremely valuable variety is perfectly distinct from any other sort. The heads are magnificent, beautifully white, large, firm, and compact, and being thoroughly protected by the foliage, remain longer fit for use than any other kind.

Price, 1s. 6d. per Packet.

LETTUCE, "EARLY PARIS MARKET."

This distinct and very handsome variety of Lettuce is much used in the Paris Market Gardens. It hearts very quickly, and we believe it will prove invaluable for forcing purposes.

Price, 1s. per Packet.

PRICES TO THE TRADE ON APPLICATION.

AMATEUR GARDENERS,

Spring, 1878.

Containing 116 pages of beautifully illustrated Letterpress, complete Directions for the successful Management of the Kitchen Garden and Flower Garden throughout the year, with Original Articles on the Cultivation of various Flowers and Vegetables, a Select List of Choice Kitchen Garden and Flower Seeds, Lilies, Gladioli, Seed Potatos, &c. Also a superbly finished Coloured Plate, the whole enclosed in a charmingly beautiful Cover of a new and elegant design.

This will be found by far the most splendid and useful Seed Catalogue ever published, and should be read by every one having a Garden.

Price 1s., post-free. Gratis to Customers.

OPINIONS FROM THE PRESS.

"For a long time Messrs. Daniels Brothers have been noted for their exquisite taste in design and colour manifested by their Catalogues, and we have to say of their *Illustrated Guide for Amateur Gardeners* for the present spring, that it is quite up to the high standard which this firm aims at." *The Farmer.*

"This is the most tasteful and best executed thing of the kind we ever remember having seen." *The Country.*

"Profusely illustrated, and the coloured plates are quite beyond the average of book illustrations." *Liverpool Mercury.*

DANIELS BROTHERS,
THE QUEEN'S SEEDSMEN,
NORWICH.

INTIMATION.

THE
YORKSHIRE NURSERY AND
SEED ESTABLISHMENT,
MALTON.

EDWARD TAYLOR

Begs to return his sincere thanks to his numerous Customers for the very liberal patronage accorded to him during so many years in the above Business, and to inform them that he has relinquished the same in favour of

MR. ROBERT BLACK,

whose great experience and practical knowledge of every department of his business enables Mr. Taylor with the greatest confidence to recommend him as his successor.

In reference to the above

ROBERT BLACK

(for some time a representative for the Lawson Seed and Nursery Company) respectfully intimates that he has purchased the old established business, and in thus beginning on his own account begs to solicit a liberal share of public support, as well as a continuation of the patronage so long bestowed upon his predecessor.

THE NURSERIES

Are plentifully stocked, and in fine condition.

THE SEED STOCK

WILL COMPRISE ALL

AGRICULTURAL and GARDEN SEEDS

OF THE

FINEST QUALITY ONLY.

CATALOGUES are in preparation, and R. B. trusts that his past experience in the Nursery and Seed Business may secure him the confidence of his friends and future customers.

ROBERT BLACK,
SUCCESSOR to MR. EDWARD TAYLOR.

SATURDAY, DECEMBER 1, 1877.

THE BATTLE OF LIFE.

INDEPENDENTLY of the attractive nature of the study, man is deeply interested in the mysteries of the "struggle for existence" among plants and animals; but it is only within comparatively recent years that we have been made aware of the universality and extent of alternate preying upon each other exhibited by organised beings, and the varied means of defence according to their several requirements possessed by different plants and animals. Some of the phenomena of weather also exercise a disturbing and destructive influence. Perhaps it is not going too far to assert that not a single species of plant or animal enjoys immunity from the predatory attacks of other plants or animals, though, of course, individuals under favourable circumstances may lead an unmolested life and die in peace and fulness of years. As all plants have enemies, either animal or vegetable, or both, it is of the greatest importance to the gardener to ascertain what they are in each case, what natural protecting agents against them the plants possess, and, in the event of their inadequacy, what artificial means can be provided to secure the perfect development of the plant. When one of the enemies has been discovered (it may be only a gardeners' enemy), it is necessary to act with circumspection, or we may by destroying a certain kind of bird favour the propagation of a still more rapacious insect. In some parts of France small birds have been almost exterminated, and the consequence is, that insects have increased enormously, some of them in the larva state destroying the crops by attacking them underground. On the other hand, in Algeria sparrows have been preserved, because it was believed that they fed upon the locusts, and now they exist in such countless multitudes that they devour the grain of acres upon acres of corn, and carry away tons of straw to build their nests.

With regard to the discovery of effective and practicable means of destroying or preventing the spread of some of the most formidable of the indirect foes the cultivator has to contend against, it must be admitted that it is much easier to say that it ought to be made than to make it. We can protect a Cabbage from a cow or a caterpillar, and the mildew of the Grape Vine is easily subdued with sulphur; but there remain, among others, two notable unconquered enemies, the one an animal and the other a vegetable organism. As may be inferred, we allude to the Vine-louse (*Phylloxera vastatrix*) and the Potato-fungus (*Peronospora infestans*). Unfortunately there appears to be no assured safety in "Salus;" but a fortune awaits the person who shall find a remedy that can be practicably and profitably applied for either of the pests mentioned. The loss these two organisms have conjointly caused is almost incalculable, and as they operate underground it is to be feared that we may have long to wait for a remedy. Still it is not impossible that some simple and inexpensive substance may yet be found to possess the desired power.

Turning to the consideration of the natural weapons and means of plants for self-preservation and for ensuring the perpetuation of their kinds, we are lost in admiration of the endless variety of provision to secure this end. But it

is a singular fact that many plants under cultivation lose their preservatives against the unfavourable influence of animals. Thus some thorny plants produce no thorns, the fruit of others changes in flavour or consistence, &c. It is true that the conditions under which plants grow in a wild state often seem to be favourable to the development of certain characteristics of a plant which also serve to protect it from agents by browsing animals or other agents. The foliage of Roses, Brambles, and White-thorn has a pleasant flavour, and would doubtless be greedily devoured by animals if not protected by prickles. In connection with this it may be observed that trees are rarely spiny; and prickly or spiny shrubs not only protect themselves, but also other plants which grow under them or amongst them. Succulent plants, such as most Cacti and the Cactus-like Euphorbias, are armed with most formidable prickles, the absence of which would leave the plants at the mercy of animals who would slake their thirst with the juicy tissues. Plants that affect a sandy soil usually develop an enormous root-system in proportion to the part above-ground, and thus not only secure a hold for themselves, but likewise prepare the ground for other species.

An efficient protection that many plants enjoy in common against the effects of cold of winter or drought of summer, lies in the capability of their seeds to bear extreme temperatures without injury, and some of them moisture for a considerable period without rotting. On the other hand some seeds soon lose their germinating force. The seed of some of the Willows, for instance, loses its vitality in a few days after it is freed from the seed-vessel. The seeds of many small edible fruits are protected from destruction by a bony endocarp, or stone, which passes undigested through the stomachs of animals, and cases are on record of such seeds retaining their power of growing even after having undergone the process of cooking. In the arid parts of Australia, where, it is asserted, spontaneous fires occasionally break out and consume or kill the greater part of the vegetation, many of the trees have hard, woody seed-vessels, which escape the fleeting flames and afterwards burst open and free the seeds. Oftentimes trees are found bearing the closed seed-vessels of several successive seasons. Perennial herbaceous plants in cold climates enjoy the advantage of their root-stocks being in a warmer medium than the atmosphere during winter. In arctic and alpine regions vegetation is covered with a thick mantle of snow during the winter months, and is thus probably never exposed to a relatively great degree of cold. The foregoing means for the preservation of plants are only a few of the innumerable ways in which their reproduction or propagation is ensured.

In the form of a supplement to the *Botanische Zeitung*, Mr. Otto Kuntze has collected an immense mass of material on the Preservatives of Plants from Animals and Unfavourable Weather. A second part of this supplement is devoted to the exposition of a theory of an original fresh-water sea; but we reserve that for notice on some future occasion. Mr. Kuntze has travelled far and wide, and his notes are many of them original and interesting. He treats of every stage of plant life from germination to fertilisation, and of the different aspects of the same species under different external conditions, in so far as they reveal means for the preservation and propagation of species or forms. One very curious contrivance for protecting seeds, as he points out, is that of ripening underground. We have an example in the native *Trifolium subterraneum*, which, after flowering, forces the seed-vessels into the ground, where the seed ripens, and grows into fresh plants. *Arachis hypogæa*, a leguminous plant, commonly cultivated in warm countries, exhibits

the same peculiarity, as does also *Geococcus pusillus*, a dwarf cruciferous plant, native of West Australia. The Sweet Flag, *Acorus Calamus*, is a plant that rarely produces ripe fruit, even in its warmest or any of its habitats (Kuntze thinks never, but its seeds are known); but like the American Water-weed, *Elodea canadensis*, it shows a most prodigious power of extension.

Trees with superficial roots, like many of the Coniferæ, usually grow very close together and thus mutually shelter each other, and they seldom have any horizontal branches of large size, so that they present very little surface to the wind. The most remarkable instance of whorled strictly horizontal branches observed by Kuntze, was in *Eriodendron orientale* (usually regarded as a variety of *E. anfractuosum*). The wind has little or no effect upon them, and in Java the telegraph wires are attached to them. As an instance of the occasional advantage of hybridism, the rapid growth of a hybrid Poplar is cited. It is a hybrid between *Populus monilifera* and *P. nigra*, var. *pyramidalis*, and grows to a height of more than 100 feet in twelve or fifteen years.

With regard to the germination of old seeds the author seems to give credence to the growth of Mummy Wheat, the history of which was written long ago. Among seeds scattered by propulsion, those of *Hura crepitans* are sometimes projected to a distance of twenty paces. The surfaces of most fruits which open with force is clammy, as in *Clusiaceæ*, &c. *Victoria regia* has the leaves thickly beset with prickles on the underside, which would serve to protect it from the attacks of "fish and other swimming animals." Plants that grow epiphytically are sometimes thereby preserved from extirpation. *Polygonum chinense* has edible berries, but browsing animals are so fond of its foliage that it is rarely met with in fruit. Birds are fond of the berries, and are the means of dispersing the seeds. Among other protective agents Kuntze speaks of stinging hairs, ants in the stems, thorns, leaf-bladders, &c., insect-food (which he regards as wholly unnecessary), hairiness, adventitious roots, secretions, &c. With regard to the change of colour during flowering, it may be, Kuntze suggests, connected with the attraction of different species of insect.

New Garden Plants.

ARDISIA OLIVERI, *sp. nov.** (Fig. 132, p. 681.)

A stove shrub, of remarkably striking appearance and of considerable botanical interest. We first met with it at Messrs. Veitch's in 1876, when we could not fail to be impressed with its peculiar recurved foliage and large globular heads of beautiful flowers like those of an *Ixora*, but of a pink colour. The plant was introduced from Costa Rica by the late M. Endres to the nursery of Messrs. Veitch, by whom it will shortly be distributed.

A coloured figure will eventually be given in the *Botanical Magazine*, meanwhile we are indebted to Professor Oliver for the privilege of figuring it on the present occasion, and avail ourselves of the opportunity of attaching his name to it, as a trifling but very sincere acknowledgment of the very valuable services he has, in a manner as thorough as it has been unobtrusive, rendered to horticultural botany for many years past.

Of personal kindness and assistance we would not speak here, but we may at least tender on the part of those who have to use the herbarium and library at Kew our heartiest thanks, and we may also congratulate both him and the public service generally on the admirable administrative capacity exerted by Professor Oliver and his assistants, and which has been so signally manifested in the transfer of the contents of the old herbarium to the spacious new building provided by Government for its reception, without interrupting the ordinary work of the department for a single day. Those who know the magnitude and complexity of the task will acknowledge that this is indeed a feat of administrative ability and whole-

* *Ardisia Oliveri*, Mast., *sp. nov.*, fig. 132, p. 681.—Glabra; foliis subsessilibus patenti-reflexis oblanceolatis integris utrinque attenuatis longe acuminatis lineis purpureis parvis notatis (20—25 cm. long., 4—5 cm. lat.); inflorescentia terminali ampla sub-globosa pilulifera e corymbis pluribus pedunculatis constans, pedunculis patentibus elongatis e bracteis; sepalis petalisque ovato-oblongis obtusis sinistorsum contortis; filamentis brevibus subulatis hirtellis e tubo corollæ prope basin emergentibus antherisque lanceolatis apice 1-poris multo brevioribus; stylo subulato stamina vix æquante.—Costa Rica, ubi legitur beat. Endres. Observ. et descript. ex specim. viv. in hort. Veitch, nec non in herb. Kew.

heartedness in work deserving of admiration. Incidentally we may mention that the rooms of the old building are undergoing re-arrangement with a view to provide for the library in a convenient manner and with special reference to the prevention of fire.

Adverting now to our *Ardisia Oliveri*, we may add a few particulars condensed from notes taken by ourselves from the living plant as well as in the herbarium. The nearly sessile glabrous entire leaves measure from 6—8 inches in length by about 2 inches in the broadest portion. In shape they are oblanceolate acuminate, and taper to the very short petiole. The general nature of the inflorescence is sufficiently shown in the illustration, technically it consists of a number of stalked many flowered corymbs. Each flower is raised on a slender pedicel about twice its own length. The calyx and corolla are both spirally imbricated to the left of the central axis of the flower (dextrorse to the observer looking at the flower). The sepals are oblong obtuse, marked with black lines; the corolla is rotate with a five-lobed limb half an inch across, the lobes obtuse, rose-pink. The stamens spring from the base of the short white or yellow throated tube of the corolla, and have short hairy subulate filaments and erect subulate-lanceolate anthers twice the length of the filaments, which open at the top by a single pore. The ovary is small, ovoid, surmounted by a long slender linear subulate style. The fruit has not yet been observed.

The present species does not fit well into any of the recognised sections of the genus established by Alphonse De Candolle in his monograph of the *Myrsinæ* in the *Prodromus*, viii., p. 120; nor by Sir Joseph Hooker in his revision of the genera in the *Genera Plantarum*, ii., p. 645. A. De Candolle's genus *Monoporus* does not appear to differ from *Ardisia*, except in the solitary terminal pore to the anther. It naturally occurred to us that our plant might be referred to this genus, but in the character of the inflorescence it is quite different to the plant described and figured by De Candolle, while the difference between one or two pores does not seem of much moment, still less the distinction between pores and chinks. Possibly De Candolle's genus *Monoporus* may ultimately form a separate section of *Ardisia*, including our present species. To importers of new plants we may, in conclusion, add that there are 200 species of *Ardisia* known to botanists, many of which would be handsome decorative plants; not a tenth or a twentieth part, however, have hitherto been seen in English gardens. *M. T. M.*

ONCIDIUM JAMESONI, *Lindl.*

A straggling inflorescence bearing many dozens of flowers forming one large yellow mass, spotted here and there with a beautiful warm violet-purple. This is the first impression this plant offers. Its upper sepals and its petals (which are highly curious, unguiculate and hastate, though in an obscure manner) have basilar or median blotches of purple. The broad pandurate lip, as well as all the other floral parts, are, no doubt, bright yellow, as in the neighbouring species, *Oncidium ampliatum*. The column has large oblong wings, ending very blunt each side, and very odd small angles are to be seen each side under the stigmatic hollow. There are innumerable small abortive flowers (see Masters' *Vegetable Teratology*, p. 462, fig. 217). The plant, I dare say, will be welcome to such amateurs as like the fascinating effect of masses of small flowers acting powerfully according to the device, *l'union fait la force*. The effect must be a good one, since M. Edouard Klaboch wished it to be dedicated to one of his best friends, provided it was new. Ah! the wish comes too late by thirty years, and many of us elder botanists like the old name that so well reminds us of an excellent friend, the Scotch Professor Jameson, of Quito, who died lately, to the great grief of so many. At all events it is pleasing to have the plant in Europe. M. Edouard Klaboch has sent it, and I have no doubt it will soon make its *début* in a big room not far from the *Gardeners' Chronicle* office. *H. G. Rehb. f.* [We are afraid not yet. EDS.]

PERILS OF A BOTANIST.

We are indebted to Mr. George Maw for the following graphic account of the dangers to which a botanist may be exposed even in the Ionian Islands. Mr. Maw's many friends will join with us in congratulating him on the result.

Landing from Corfu early on the morning of October 28, I at once called on a gentleman connected with the commercial community, to whom I had a letter of introduction, to make inquiries for accommodation. Thence proceeded to the little hotel and breakfasted, but the 28th being Sunday, I deferred my intended visit to the Consul.

After arranging with the hotel-keeper to obtain me a horse and guide for a botanical excursion in the island on the following day, I went out for a walk to the hill

FIG. 132.—ARDISIA OLIVERI, NATURAL SIZE ; FLOWERS ROSE-PINK.

south of Phanaromanie, overlooking the town, and, tempted by the beauty of the scenery and the interesting surroundings, wandered on for two or three hours through vineyards and villages to Asproierakata, where, at a point about twenty minutes' walk above the village, five young men surrounded me and commenced importuning me for money, and immediately rifled two of my pockets with a demonstration of force which I felt it unwise to resist, though no actual violence was exercised. The men at once hurried off with their booty towards the coast, and I retraced my steps to the village, where the Demarch, or village mayor, suspecting that something had happened, spoke to me, and, with the assistance of a man who understood a few words of English and Italian, was soon made acquainted with the circumstances. The Demarch and villagers urgently desired me to remain the night, with the object, I afterwards ascertained, of endeavouring to recover my money without the transaction becoming public. I, however, insisted on returning to the town, and, accompanied by the Demarch, reached the Consulate at a quarter to six, where Mr. Onofrio, the Vice-Consul, heard with much surprise the particulars of the robbery, as the Ionian Islands were looked upon as perfectly safe, nothing of the kind having occurred in Santa Maura since the year 1838, when a serious conflict with the English troops took place.

A hasty memorandum of the particulars of my loss was made at the Consulate, whence we repaired to the office of the Procurator Fiscal, where the whole of the public authorities of the island, including the Eparch or Governor, the assistant Public Prosecutor, the Commandant of the Fortress, the Chief of Police, the Demarch or mayor of the town, and other functionaries soon assembled. I cannot speak too highly of the tact and judgment displayed by Her Majesty's Vice-Consul in representing the urgent necessity of prompt redress, met by a ready compliance on the part of the authorities, who at once assured me that the money would be recovered and the men taken within a few hours. Full and minute depositions were taken as to the contents of the stolen purse and pocket-book, even to the number and value of each kind of postage stamps.

At 10 P.M. the Public Prosecutor requested the Commandant to at once provide 120 soldiers, said that he could capture the men with ten, but that he had an object in taking up an imposing force. The Demarch of the town was desired to obtain horses for the public authorities, H.M. Vice-Consul, and myself; but few were forthcoming. It was said that the villagers of Asproierakata form part of his municipal constituency, and that he wished to favour them, by gaining time for the voluntary restitution of the stolen property.

A rumour now reached us that the stolen money was already in Santa Maura, and at a few minutes after 10 P.M. the priest of the village appeared, bringing with him a little rag bundle, given him by a person he declined to name, containing £29 in English gold, some Italian and Austrian notes, postage-stamps, and silver and copper coin, mixed up together, all of which was counted, and, as far as I could remember, fell short of the amount stolen by from £15 to £18. An English £5 Bank of England note, and eight or nine 25 franc Greek notes were certainly missing. The priest had been previously with the stolen property to the Demarch of Santa Maura, and from information I received after leaving the island I have reason to believe that it had closely followed me from the scene of the outrage, and reached Santa Maura within an hour after my return to the town, as a rumour was afloat between 6 and 7 o'clock that the stolen money had been brought for restitution, no one knowing to whom it belonged.

The Public Prosecutor decided promptly that the balance of the stolen amount must be restored, and the men captured, and we were requested to hold ourselves ready to start for the scene of the robbery.

After an hour's rest and a hasty meal, we reassembled at midnight, and with soldiers, constabulary, and the authorities, we formed a long column of about 160 men in the main thoroughfare, and marched on into the shade of the dense Olive grove environing the town. This was planted under the rule of the Venetians in the seventeenth century. A golden sequin (about 9s. 6d.) was paid as a premium to encourage the culture of the Olive on every established tree, and the trees are so thick that they are barely fruitful. The scene was novel and strange, the dull rays of the half-moon obscured by driving clouds and filtered through the dense overhanging Olive boughs, here and there cast an occasional glimmer on the soldiers' rifles, mixed up confusedly with the cigarette lights and the glow-worms; the suddenness of the occurrence, and the strangeness of the scene became almost oppressive to the "outraged British subject," who could scarcely realise that he is the central feature of such a demonstration. We marched on and on for three hours, out of the Olive wood, and wound up some 1500 feet, through vineyards, and at last halted about three o'clock in the morning near the village of Sphakioties, where the 120 soldiers were detailed in small companies to completely invest the offending district. Some of us retired

to rest in the house of the Demarch, the Public Prosecutor remaining at work all night.

October 29.—Last night's driving scud developed into a dull melancholy day, and a saturating moisture of mingled mist and pouring rain, but the soldiers had already done their work completely. The vineyards were deserted, and scarcely a man was to be seen. The male population of the district was apprehended, and was in captivity, but where? My companion said "Would you like to see them?" and took me up the hill to the little church, which, with the surrounding churchyard, was densely packed with an exceptionally large congregation, like sheep in a pen. The scene was bewildering, and I could not help exclaiming, "Oh, what a lot!" But this was not all. My friend pointed to a knoll a little way off, and through the mist I saw an ill-defined dark patch, another churchyard full of men, and the mass threading out in procession towards me. Each man was passed in review for identification, and I picked out one, who admitted he saw the deed committed. The priest who brought in the first portion of the stolen money refused to give up the name of the person from whom he received it, and was placed under arrest, but as he was still obdurate and uncommunicative, the Public Prosecutor sent him a message to the effect that if he wished to speak the truth he might speak in Greek; but if not, he had better communicate in Chinese. He at once elected to speak in his native tongue, and gave the desired information.

The whole of the five men were at last identified, and three in actual custody in the town of Santa Maura. The soldiers were told off for billet in the various houses, and the men liberated and called before the Public Prosecutor, who addressed them, and told them that the 120 soldiers would remain at their expense till the whole of the five men were in custody and the remainder of the stolen money restored, and that at the end of three months a further contingent of fifty men would be added to the little army they were supporting.

A rumour reached us at 4 P.M. that the pocket-book and remainder of the money had been taken to Santa Maura, but the amount, about £20, was certainly more than the balance of my loss. A special messenger was sent to ascertain particulars, and at the request of the troops the three prisoners were brought back to the scene of the outrage, that as they had contributed to their capture they might have the satisfaction of publicly escorting them into Santa Maura.

The evening of October 29 was pleasantly spent at Sphakioties, with the various civil and military authorities; "Health to the recovered money" was drunk in rabe, and the lieutenant commanding the troops, who as sergeant led a portion of the soldiers who captured the Marathon brigands, gave us a graphic account of the transaction, and told us how he tracked them over the snow, and with fifteen men against twenty-six killed four and wounded two without losing a man, and drove the remainder of the band to surrender. I also learnt much about the inner life of Santa Maura. Almost the whole of the inhabitants are well-to-do peasant proprietors, and each village is self-contained, almost independent of the outer world. They produce nearly every necessary of life—corn, wine, oil, meat, and fuel, and every article of clothing, except cloth, is produced in the house. They grow their own Flax, Cotton, Hemp, and wool. The matrons of the household have distaff and spindle in hand, and the home-made loom works the thread up into coarse calico, towelling, and blankets and rugs of no mean artistic merit. The natives of Sphakioties, where we lodged, especially the women, are comely and of fine stature, of a different race to the remainder of the islanders, and the descendants of a colony from Spakia, in Crete, which was imported by the Venetian nobles in the fifteenth century.

October 30 opened with a lovely, brilliant morning, after yesterday's gloomy rain, and the lifted veil of mist revealed a scene in fair Leucadia more beautiful than any description can convey. We looked down from the hill above the village over a rich foreground of vineyards, golden and crimson in their autumn leafage, relieved by the contrast of tall green Cypresses. To the south the finely moulded grey ridge of Megaoros, culminating in the point of Saint Elias, with a distant portion of the Peloponnesus, bounds the view. To the east the mountains of Epirus and Albania, backed up by the range of Pindus, which last night received its first mantle of snow, were seen over the Turkish town of Previsa, and the Gulf of Arta running far inland to the foot of the mountains, and to the north the faint outlines of Paxos and Corfu resting on the bright blue Ionian Sea. In the early morning we marched from Sphakioties to the village of Asproierakata, and by mid-day the five men were all in custody. Formal depositions were taken at great length by the Public Prosecutor, and the prisoners committed for trial. At 3 P.M. the five men, roped together, were sent forward under a small guard, followed by the public authorities and troops, and winding down through the vineyards and the Olive wood shrouding the plain we reached the town of Santa Maura at nightfall, through a dense crowd which had turned out to meet us, the whole

transaction, from the robbery to the apprehension of the men and the recovery of the lost money, having been accomplished within forty-eight hours.

The affair created intense anxiety and indignation throughout the island, not only amongst the commercial community of the town, but everywhere during my subsequent excursions in the island the expressions of respectful sympathy and regret were universal. Before my departure the parents and other relations of the young men called upon me to ask my forgiveness. I explained to them that the matter was not in my hands, that I felt such an offence ought to be punished, and would be severely punished in my own country, but that, as the robbery could not have been premeditated, and as prompt reparation was made, I would ask Her Majesty's Vice-Consul to intercede for such a mitigation of the penalty as the tribunal might consider consistent with the circumstances. *George Maw, Benthall Hall, Brassey.*

THE GENUS AGAVE.

(Continued from p. 60.)

SERIES II.—*CARNOSO-CORIACEÆ*.—Texture of the leaf more fleshy and pliable than in the *Coriaceo-carnosæ*. End-spine scarcely pungent. Prickles if present always small.

Group VIII. *ALOIDEÆ*.—Edge of the leaf furnished with distinct teeth.

In the present paper I propose to deal with the large species of this group, which have oblanceolate-oblong or ensiform leaves. These differ from the *Aloideæ* already dealt with by the leaf being narrower in proportion and less narrowed at the base, and from those of my next paper by their larger size.

* Leaves oblanceolate-oblong.

70. *A. (Littæa) Goeppertiana*, Jacobi, Monogr., p. 243 and 308.—Stem reaching a height of $\frac{1}{2}$ a foot. Leaves 20–30 to a rosette, oblanceolate-oblong, 2 feet or more long, 4–5 inches broad at the middle, narrowed to 3–3 $\frac{1}{2}$ inches above the base, bright green, the face rather hollowed, the short brown tip pungent only in the young state, the crowded spreading brown deltoid teeth under a line long, the base about 1 inch, the centre $\frac{1}{2}$ inch thick. Scape twice as long as the leaves, densely clothed with adpressed lanceolate bracts. Flowers in a dense spike as long as or longer than the scape. Perianth including the ovary 1 $\frac{1}{2}$ inch long; ovary oblong, 8–9 lines long; segments oblong-lanceolate, about as long as the tube. Filaments 21–24 lines long, inserted at the throat of the tube; anthers $\frac{1}{2}$ – $\frac{3}{4}$ inch long. Style nearly 1 inch longer than the filaments. Mature capsule oblong, $\frac{3}{4}$ inch long.

A native probably of Mexico. Described by Jacobi in 1865 from specimens sent in Breslau and Reigate. There is a figure of the plant in flower in the seed-index of the Breslau garden for 1874. There is a small specimen in the Kew collection.

71. *A. Smithiana*, Jacobi, Monogr., 250.—Acaulescent. Leaves about thirty in a rosette, oblanceolate-oblong, 4 inches broad at the middle, narrowed to 2–2 $\frac{1}{2}$ inches above the base, bright green, the face flat in the centre, 1 inch thick at the base, $\frac{1}{2}$ inch at the middle, the brown tips $\frac{1}{2}$ inch long, the close deltoid brown prickles about $\frac{1}{2}$ inch long. Inflorescence unknown.

Described by Jacobi in 1865 from a specimen in the Kew collection, imported from San Luis Potosi, and named in compliment to Mr. Smith. I have seen it only in the Kew collection, and cannot separate from it by the descriptions, *A. lamprochlora*, Jacobi, *Nachtrage*, i., p. 35, and *A. perlucida*, Jacobi, *Nachtrage*, i., p. 36.

72. *A. (Littæa) horizontalis*, Jacobi, *Nachtrage*, i., p. 33.—Caulescent. Leaves few, oblanceolate-oblong, 2 feet long, 4–5 inches broad at the middle, narrowed to 2 $\frac{1}{2}$ inches above the base, the face broadly channelled, bright light green, glaucous when young, the end-spine short and chestnut-brown, the edge not at all repand, the crowded minute deltoid teeth dull chestnut-brown. Scape 3–4 feet long. Flowers in a dense spike 2–2 $\frac{1}{2}$ feet long, the lower bracts about 4 inches, and the upper about 2 inches long. Perianth under 2 inches long, the ovary about $\frac{3}{4}$ inch, the oblong-lanceolate reddish-brown segments equalling the tube. Filaments 2–2 $\frac{1}{2}$ inches long; anthers 9–10 lines.

Described by Jacobi in 1865 from a flowering specimen in the collection of Mon. De Jonge van Ellemeet, of Overduin in Zelande, received from the Botanic Garden at Utrecht. Although Mons. Ellemeet raised a couple of hundred seedlings, I have not seen it in any of our English collections.

73. *A. Humboldtiana*, Jacobi, Monogr., p. 251.—

Acaulescent. Leaves 30—40 in a rosette, oblanceolate-oblong, $2\frac{1}{2}$ —3 feet long, 5—6 inches broad at the middle, narrowed to 3 inches above the base, bright green, slightly glaucous when young, slightly channelled in the centre, the base a couple of inches, the centre $\frac{1}{4}$ inch thick, the brown end-spine about $\frac{1}{2}$ inch long, the red-brown close very minute deltoid prickles tipped with red-brown. Inflorescence unknown.

Like *A. Smithiana*, this was described by General Jacobi on his visit to England in 1865 from a specimen in the Kew collection imported from San Luis Potosi. The plant is still at Kew, and has never flowered.

74. *A. kewensis*, Jacobi, Monogr., p. 242.—Stem $\frac{1}{2}$ foot high. Leaves 30—40 in a rosette, oblanceolate-oblong, 4 feet long, 7—8 inches broad above the middle, narrowed to 4 inches above the base, bright green, $\frac{1}{4}$ inch thick at the base, $\frac{1}{2}$ inch thick in the centre, the end-spine short and brown, the face hollowed all down, the prickles small, distant, deltoid, brown, spreading. Inflorescence unknown.

A native of Mexico. Described by Jacobi in 1865 from a specimen in the Kew collection, which is still there, and has never flowered. It is by far the finest of all the *Aloideæ*.

* * Leaves ensiform.

75. *A. (Littæa) Sartorii*, K. Koch; Jacobi, Monogr., p. 128; Bot. Mag., t. 6292; *A. Nozckii*, Jacobi, Monogr., p. 125; *A. pendula*, Schnittspahn; Jacobi, Monogr., p. 130; *A. caspitosa*, Todaro, Hort. Bot. Panorm., t. 8.—Caudex 1—2 feet long, sometimes forked. Leaves 30—40, spaced out in a lax rosette $1\frac{1}{2}$ —2 feet long, 3 inches broad at the middle, narrowed to 2— $2\frac{1}{2}$ inches above the base, bright green, with a pale band down the middle, 1 inch thick at the base, $\frac{1}{4}$ inch thick in the centre, the face flat, the end-spine small, and not pungent, the minute, crowded deltoid spreading teeth tipped with red-brown. Scape 3—4 feet long, the green linear ascending bracts 2—4 inches long. Flowers in a dense spike about 3 feet long, 5—6 inches broad when expanded. Pedicels very short. Perianth greenish, $1\frac{1}{2}$ inch long, including the ovary. Ovary, tube, and segments of about equal length. Filaments 18—21 inches long, anthers $\frac{3}{4}$ — $\frac{1}{2}$ inch long. Style rather exceeding the filaments.

A native of Mexico and Guatemala, introduced about 1860. It is now widely spread in collections, and has flowered several times. A full account of the plant will be found in the *Botanical Magazine* just cited, from a plant that flowered at Kew in February, 1877. I cannot distinguish by the description *A. rufocincta*, Jacobi, *Nachtrage*, i., p. 88.

76. *A. (Littæa) oblongata*, Jacobi, *Nachtrage*, i. p. 40.—Acaulescent. Leaves ensiform, 2 feet long, $3\frac{1}{2}$ inches broad at the middle, narrowed to 3 inches above the base, light glaucous green, the face nearly flat in the centre, the end-spine small, weak, and chestnut-brown, the edge not at all repand, the teeth crowded, minute, deltoid, chestnut-brown. Scape 4 feet high, 1 inch thick at the base. Flowers in a dense spike, which is twice as long as the barren part of the stem. Perianth $1\frac{1}{2}$ inch long, including the ovary; segments $\frac{3}{4}$ inch long. Filaments $2\frac{1}{2}$ inches long; anthers $\frac{3}{4}$ inch long. Style rather larger than the filaments. Capsule elliptical, $1\frac{1}{4}$ inch long.

A native probably of Mexico. Described by Jacobi, in 1868, from a specimen received from Herr Tönel. It is, I think, most likely a mere variety of *A. micracantha*. I have not seen it in England.

77. *A. (Littæa) Haseloffii*, Jacobi, Monogr., p. 244.—Shortly caulescent. Leaves about twenty in a rosette, lanceolate, reaching a length of 18—21 inches, 3 inches broad at the middle, narrowed to 2 inches above the base, bright light green, $\frac{1}{2}$ inch thick at the base, $\frac{1}{2}$ inch in the centre, the brown subpungent end-spine $\frac{1}{2}$ inch long, the teeth close and brown, the central ones lanceolate, $\frac{1}{4}$ inch long, those of the lower two-thirds of the edge more or less deflexed. Stem 5 feet long, $1\frac{1}{4}$ inch thick at the base. Flowers in a dense spike about 2 feet long. Perianth bright green, $1\frac{1}{4}$ inch long, including the ovary; ovary $\frac{3}{4}$ inch long; segments about $\frac{1}{2}$ inch. Filaments $2\frac{1}{2}$ inches long; anthers $\frac{3}{4}$ inch long. Style rather longer than the filaments.

A native probably of Mexico. Described by Jacobi in 1864 from a specimen in the garden of the gentleman after whom it is named. In England I have seen it at Reigate and Kew, but only in an undeveloped flowerless condition.

78. *A. (Littæa) Muilmanni*, Jacobi, *Nacht*, ii., p. 76.—Shortly caulescent. Leaves lanceolate, 2 feet or more long, 2— $2\frac{1}{2}$ inches broad at the middle, bright green, the face concave, the end-spine horny and red-brown, the edge not at all repand, furnished with minute crowded

deltoid red-brown horny teeth. Scape, including the inflorescence, 4—5 feet long. Flowers in a dense spike half as long as the barren part of the stem. Perianth, including the ovary, 16 lines long; ovary about $\frac{1}{2}$ inch, segments above $\frac{1}{2}$ inch long; tube very short. Filaments $1\frac{1}{4}$ inch long; anthers linear, $\frac{3}{4}$ inch. Style as long as the filaments.

A native probably of Mexico. Described by Jacobi in 1871, from a plant in the collection of Herr Müllmann at Utrecht. I have not seen it in England.

79. *A. Murtiana*, K. Koch; Jacobi, Monogr., p. 116.—Acaulescent. Leaves lanceolate, reaching a length of 2— $2\frac{1}{2}$ feet, 3— $3\frac{1}{2}$ inches broad at the middle, narrowed to 2 inches above the base, a light opaque green, the face nearly flat when mature, the end-spine very short and brown, the edge in the upper part with a continuous brown line and minutely toothed, lower down furnished with irregular small deltoid chestnut-brown teeth. Inflorescence unknown.

A native probably of Mexico. Described by Dr. Karl Koch in 1864, from specimens in the Botanic Garden at Berlin.

80. *A. caribæa*, Hort. Kew.—Acaulescent. Leaves about thirty in a rosette, ensiform, 2— $2\frac{1}{2}$ feet long, 3— $3\frac{1}{2}$ inches broad at the middle, $2\frac{1}{2}$ inches broad above the base, narrowed gradually from the middle to a weak brown point about $\frac{1}{4}$ inch long, bright green, the face nearly flat, the centre $\frac{1}{2}$ inch, the base 1 inch thick, the prickles very close and very minute (the central ones only $\frac{1}{4}$ — $\frac{1}{2}$ line long), deltoid, all pale green, or only faintly tinted at the very tip with red-brown.

History unknown to me. Described from two specimens now in the Kew collection, received one from Reigate and the other from Mr. Justus Corderoy. *J. G. Baker*.

COLOURED LEAVES.

SEING the other day a glass, the foliage in which consisted of autumn leaves, it occurred to me that an effective and varied nosegay might be formed of leaves whose form and natural colours, without the fugacious aid of autumn, might be the most interesting of the two. Azalea leaves have no beauty in themselves of form or texture, although an American garden I saw the other day was as bright with red, crimson, and purple foliage as in June, when the Azaleas are a blaze of yellow, orange, flame, and pink flowers.

The leaves I collected were, for feathery, hair-like texture, *Ferula tingitana*, *Meum athamanticum*, two *Tanacetums*, boreale and crispum, *Acæna millefolium*, *Achillea Millefolium* and *A. M. variegata*; of round Geranium-shaped leaves there were the chocolate *Heuchera Richardsoni* and *Tellima grandiflora*; a stalk of *Epimedium rubrum*, which oftener has leaves in a beautiful marbled state than the other *Epimediums* we have; a leaf of *Burnet* and *Spiræa filipendula*, a gold feather leaf of *Potentilla asserina aurea*, and one of *Barbarea vulgaris variegata*; *Cineraria acanthifolia* and *Artemisia argentea* were two grey leaves, and a forked leaf of *Peucedanum officinale*; one stalk of *Woodruff* for the seven-rayed star of its whorled leaves, and a blade or two of *Carex japonica variegata* and *Dactylis glomerata variegata*; also one *Juncus spiralis*, to give point to the group, and a miniature Palm leaf, as in *Helleborus fetidus*, of darkest green, and one of *Rubus laciniatus*. The whole formed a glass of varied beauty, and relieved the eye, the other glasses being full of brightest Roses, *Chrysanthemums*, *Asters*, *Gladioluses*, *Anemone japonica* of sorts, *Stocks*, *Antirrhinums*, &c. The leaf glasses have lasted three supplies of flowers, and look as if they would last another three. As I write they attract me irresistibly, the beautiful forms and delicate and varied textures are charming.

In regard to the fading of green leaves it is interesting to note how very many fade into as bright colours as any one sees in flowers (with the exception of blue), and how few flowers fade into beauty, all their varied colours and shades merely dying into dingy drabs, browns, and white—but then green is not a colour, but a substance. I can only remember at this moment *Vittadenia triloba*, *Aster discolor* and *bicolor*, and *Franciscæ*, the young and old flowers of which one has to recollect before pronouncing which is the normal colour; the white to pink of *Vittadenia*, white to purple of the *Asters*, and lilac to white of the *Franciscæ*. It is a good quality, this changing of colour, and prolongs the beauty of a flower. *L. J. Hope, Wardie Lodge*.

PICTURESQUE PLANTING.

THE planting of woods or waste lands with a view to profit is a very easy matter, and may be carried out by any one having only a very limited knowledge of trees, but to produce the most pleasing artistic effect, and add to the natural beauties of a landscape, requires much study and an intimate acquaintance with the different species, their habit and growth, or the arrangement of them must necessarily be of a haphazard kind, as may be seen in the incongruous mixtures frequently to be met with in many of our parks and pleasure-grounds. If half the skill were brought to bear on work of this kind that is now expended in carpet bedding and other modes of embellishing flower gardens, what splendid results would be achieved, not of the ephemeral character of that which endures only for a season, but such as the hand of time would improve and render still more beautiful.

We have plenty of hardy plants, if they were only used as they deserve to be, that would form strikingly ornamental objects grouped or placed in suitable positions, as may be seen by any one visiting such establishments as those of the Messrs. Veitch at Combe Wood or others of our large nurserymen. Take the Bamboos, for instance, and what can be more graceful than their long tapering rods drooping in a regular curve, with the tufty sprays of elegant green foliage always kept in gentle motion by the slightest breeze or breath of air that is wafted. Such a plant on a lawn or near water is quite cooling and delightful to look on during a hot summer's day, and not only then, but being of such distinct habit, they show up most favourably with anything with which they may be associated, and impart quite a cheerful aspect to any garden at all seasons of the year. Then, again, there is that fine hardy Palm, *Chamærops excelsa*, a few of which judiciously grouped or planted as isolated specimens in certain positions would impart quite a tropical appearance to any place, and yet strange to say it is rarely met with anywhere except under glass. Of a different type of vegetation, but equally effective, are the different varieties of *Yucca*, some of which in addition to their ornamental foliage and stately growth produce annually fine spikes of magnificent flowers. The whole family are plants well deserving a much more extended cultivation than they now receive, and from their hardy nature and sturdy habit are specially adapted for elevated positions in poor soils, where, whether bleak or not it matters little, as they struggle on quite regardless of storms or sunshine. Even with these alone, and a few evergreens to back them up, a fine effect might be produced in certain portions of the grounds, especially where at all broken up either naturally or artificially, as then they can be grouped according to their several habits, and made to show off to great advantage.

For sunny spots on lawns as single plants or to form masses in prominent parts of the shrubbery border, what can surpass the *Rhus Cotinus* with its brilliantly coloured feathery inflorescence, almost equal in appearance for lightness and elegance of form to the plumes of the ostrich?—and yet there are hundreds of places where this beautiful shrub is not to be found. The *Sumachs*, too, although they have not so much to recommend them as regards flower, amply make up for that deficiency by the rich profusion of their elegant foliage that furnishes such fine autumnal tints, of which, alas! the early frost and gales have this season unfortunately robbed us. Another strikingly ornamental and much-neglected plant that has been noticed of late in the pages of the *Gardeners' Chronicle* is *Arundo Donax*, so easy and graceful in outline that it cannot well be misplaced, as it is alike suitable for the extreme back of shrubbery borders, single specimens or groups on lawns, the subtropical garden or Fern dell, but where it looks more particularly at home is near lakes or ponds associated with *Pampas-grass*, Bamboos, &c.

If we want variegated plants, or such as have beautiful foliage, for producing pictorial effect in the more dressed portion of the grounds, there are now any quantity, of either erect or spreading habit, varying in size from the tiny *Euonymus radicans* up to others of giant stature; so that with a little study and foresight there need be no difficulty in so blending them as to come in to suit spring, summer, autumn and winter, and thus render the aspect of a place attractive at all seasons. What is in my opinion so much needed is a more bold style of planting instead of the

liggledly-piggledly system that now to a great extent prevails, apparently without any regard to contour or their suitability for each other. Take, for instance, the usual run of places that have been planted without professional aid being called in, and what do we find but a Laurel here, a Holly there, with Thorns, Planes, Conifers, and other things dotted about in endless confusion, and so near together that in a few years many have to be sacrificed. If, instead of this, plants that harmonise were grouped a little together, how much more pleasing the effect would be. Suppose we take for example a background of the common Yew, *Taxus baccata*, and plant in front any of the gold or silver variegated kinds at suitable distances to allow room for growth. The effect of these, as soon as they got into size, would be to light up a place in such a manner as to be satisfactory to the eye at all seasons. Green and variegated Hollies might be used in the same way, and so on with many others, but of course this kind of planting may be carried to an extreme, and become of too formal a character.

The thing is with this as with all other modes of embellishment, to get contrast and perfect harmony at the same time, as well as that natural ease of outline that trees and shrubs always assume when properly arranged. Among plants capable of producing those lovely tints during the autumn that all of us so much admire, the American Oaks, Liquidambar, Sugar Maple, Sorbus, Birch, with its polished papery bark, and *Pavia flava*, should have conspicuous places, as should also those having variegated or ornamental foliage, such as the Fern-leaved Beech, Fern-leaved Elm, Willow-leaved Oak, &c., and among the former, gold and silver Elms, Acers, Thorns, and Willows, all of which do much to enliven a place. For clothing trees that are thin of branches, or have become decrepid through age or other causes, nothing can equal some of the Vines, the Virginian Creeper, Traveller's Joy, and some of the free-climbing Roses, the effect of which when seen festooning in a natural way from such lofty positions is really most charming. Some we have here treated in that way are of the most picturesque character imaginable; and so exceedingly telling are they for certain situations that it is quite worth while sacrificing a few common trees for the purpose of growing them. Vines especially, that have such gorgeously beautiful leaves during the autumn, are most striking, as is also the old Virginian Creeper and *Ampelopsis Veitchii*, both of which colour up most brilliantly when fully exposed to sunlight and air. Some of the Ivies, too, are very showy, and associate well with any of the foregoing, to which they likewise show up in pleasing contrast.

Leaving the pleasure-ground for the park, what grand effects may be produced here by a little grouping and blending of colour, such, for instance, as would be afforded by the Abele and Copper Beech, neither of which are half so much used as they deserve, if we take into consideration how very ornamental they are. An avenue of the latter planted here will be quite a feature some day, and besides being particularly suitable for this work they look well near silvery streams and lakes, or on hill-sides, either in masses or as single specimens.

Magnificent as are the English Oak and Beech for park scenery, the landscape would look cold and drear without some trees of an evergreen nature, and none stand out in bolder relief than the Scotch Fir, which from its rugged appearance and powers of endurance is just the thing to clothe the hill-top or other bleak exposed situations. Of all the Conifers I look on this, after it attains size and age, as the most picturesque, especially when planted in clumps of from three to five or six, and within a few feet of each other. Such a group would delight any artist, and form a pleasing picture in any landscape, as there is something in the trees when so arranged that looks so natural; and more particularly is this the case if they vary greatly in size, giving one the idea that the smaller have originated from those of larger stature. These being of a dark sombre hue, the grey of the Deodar and the silver come in well, but owing to the early spring growths the former make it useless, except for sheltered situations. Besides a judicious commingling of foliage in planting to produce picturesque effect, much may be done by taking advantage of the ground, the inequalities of the surface of which should be seized on to make the valleys look still more depressed, and the mounds or hills still higher by planting on them only such things

as tower up, except toward their base, to which the gradation ought to be carried by using others of more lowly growth. If this is strictly carried out it gives a much more broken and diversified surface, and an apparent extent that could not be produced in any other way, besides which there is a degree of natural beauty about such planting of which the eye never tires, as there is always repose in the depth of light and shadow and the many-coloured tints of the foliage. *Y. S.*

CYPRIPEDIUM INSIGNE MAULEI.

At one time or another in almost every establishment where the liking for a collection of Orchids is a growing passion, the probability is that in one of the earlier stages of such a gathering or accumulation *Cypridium insigne* will be found to have had a place; and though, by the arrival of other and certainly more showy forms and species, it may now be esteemed of less importance and value, it will always in some of its varieties be deserving of a place in the most select and choice collections. That there are two or three distinct varieties of it will be apparent to most growers, though to determine which are true to name by the manner of growth or the general habit of the plants is a matter of very great difficulty, and any attempt to prove them by this means would almost certainly result in failure and disappointment.

There is certainly a small-growing variety, the leaves of which are narrower and the flowers considerably less in size than the original type, which will be readily recognised though it is not often met with; but when we come to the others, the growth is so exactly alike that it is only by accepting the word from those of whom they are obtained that any particular plant can be received as just the one variety that is desired. These thoughts and allusions are prompted, and in fact necessary, by a reference to some made in the *Calendar of Operations* at p. 495, where, in treating of this species, reference is made to two forms that had been obtained under the names given, and were described and recommended accordingly. That *C. insigne* Maulei was and is distinct has always been accepted as an assured fact, yet a doubt as to its true characteristics was so often expressed that one was as often left undecided as assured that the description was true and satisfactory. That the doubt may be cleared up, and the true markings of this variety known (for the time being I will not allude to those I have under my charge here), I may state that I have succeeded in obtaining flowers from different collections, which are now before me, and comparing one with another find the following to be clear and unmistakable. From the plant of the one named *violaceum punctatum*, which at the time of the Manley Hall sale passed into the collection of the late Mr. W. B. Hume, I have succeeded in obtaining a flower, kindly forwarded by the present gardener, Mr. A. Murrel, who assures me that his late employer considered it by far the best variety he had. I have also been favoured with a flower of the true Maulei by the Messrs. Veitch & Sons, of Chelsea, the same as exhibited by them at the floral meeting of the Royal Horticultural Society on the 6th inst. (see p. 600). Placing these side by side I find them so exactly alike in size, colour, marking, and purple spotting, that one is tempted to inquire, Which can be the true plant now?

Well, from the Messrs. Maule, of Bristol, I have been able to obtain the *Floral Magazine* for July, 1861, and there on the first page is a figure of the original Maulei, and a statement that the drawing had been made from a plant exhibited by the Messrs. Maule at one of the meetings of the Royal Horticultural Society during the autumn of 1860, and was then awarded a First-class Certificate. On comparing the flowers with the plate all uncertainty is at once removed. Here we have the true Maulei in both cases, and the name *violaceum punctatum*, though it may be very true as far as description in a limited sense is concerned, is quite unnecessary and misleading, and would be better dropped altogether. Comparing the flowers with those of *insigne*, the lip or slipper part is narrower at the point—the whole of this part being of a bright shining brownish purple colour, the petals a good part of their length being stained with a similar colour, and shining as the lip. In the words of the work just quoted, which are as true now as when the plant flowered for the first time, we may

say:—"It is a really handsome and attractive form of this well-known species, differing most obviously in the broader surface of pure white on the dorsal sepal, and in the purple spotting which occurs on this white ground, quite distinct from the brownish spots which only are met with in the ordinary states of this species. The spots, moreover, are more distinct, larger, and less numerous than usual, and fully two-thirds of the surface of the sepal is white."

Little need be said beyond this in praise of this fine variety. However, to those whose taste is towards this class of plants, it may truly be said to be one of the most pleasing, showy, and desirable forms that are to be met with in this group or section of *Cypridiums* bearing single blooms. *W. Swan, Pallowfield, Nov. 20.* [The description and plate above referred to having been drawn up and published by one of us, we can endorse as correct all that Mr. Swan states as to the distinctness and beauty of this variety. *EDS.*]

ROOT-PRUNING.

It is pleasing to note the kindly and philosophical spirit in which this matter has been discussed in your pages. It is one of the most important subjects that can engage the attention of horticulturists. Mistakes, too, are very pardonable in regard to this matter, for the theory and practice of root-pruning are comparatively recent additions to the art of horticulture. It has also proved itself one of the most potent and successful means of hastening and augmenting fertility. Top-pruning may succeed, root-pruning must; in rendering fruit trees fertile the former deals with vital power and growth after both are made, the latter moulds it in the making to the will of the cultivator. So far these are facts, not theories. Root disturbance, lifting, pruning, forces vitality to the side of fertility. This is a matter of daily experience. A young tree rushes into wood growth; prune the top, it makes more and stronger wood—prune its roots, it stops growing timber and sets about the work of fruit bearing. Hence I cannot at all agree with Mr. Hinds, that top-pinching is equal to root-pruning as a means of forcing trees into fertility; though what he says at p. 598 is quite true—that top-pinching will force the strong shoot to break into two or three instead of one. But this mere weakening of the shoots may not end in fruitfulness. A number of weak shoots not seldom continue as sterile as fewer and stronger ones. Fertility is something more than the mere product of a sub-division of growing force. Our gardens and orchards abound with barren sprays as well as sterile boughs. Pinching in our climate often proves a mistake; our summers are barely long enough to ripen one crop of wood, to say nothing of two or more. A crop of medium-sized shoots furnished with immature buds is but a poor basis or preparation for fertility. Besides, persistent stopping probably throws the roots out of gear, as it were, in regard to their season of active growth. Sever a big root and you modify top growth at once. There is no proof, however, that the converse holds good. Pinch or prune back a strong shoot and the root does not follow the lead of the top and break into fibres, but holds on its course as an earth cleaver or a water carrier. This is the testimony of actual experience demonstrated by actual practice.

Few admired or were influenced more by the practice and the writings of the great and good man so lately removed from us, Mr. Thomas Rivers, than the writer. As a consequence I went with enthusiasm into the pinching theory, and found it a mistake in the open air. With the command of an artificial climate in orchard or other glass houses it may succeed—in the open air, writing broadly and admitting many exceptional cases of success, pinching fruit trees more than once, and that so late in the season as to prevent a second crop of wood, is and has all along been a mistake. It is impossible thus to force fertility at the point of the knife, or finger and thumb on the tops of trees; besides, there is no need of it. The root-pruner has the issues of growth and of produce entirely in his power. He wants timber—let him plant his trees, or, better still, sow the seeds of them, in rich soil, and leave their roots alone, and feed them liberally, and he will have it. He plants for fruit—let him plant on medium soil, sever the strongest roots at planting, encourage them to run within a foot or so of the surface, and lift or prune them occasionally—if they run into water-pipes instead of fibrous masses—and fruit in plenty, weather

permitting, will be as certain to follow, as that twice two are four.

Diverging from demonstrative facts to their probable causes, theories are at once broached that may be open to question, but these do not alter the facts any more than erroneous notions concerning light can extinguish the sun at noonday. The sun shines on all the same, whatever our theories of the manner of his shining, and in like manner root-pruning promotes fertility, though we may be in profound ignorance of some or all of the causes of this result. For instance, perhaps my views were open to the objection urged by Mr. Hinds with regard to time. Possibly it might have been rather too late to modify the buds much for this season, but root-pruning is useful to augment fertility as well as to produce it, and the moment the large roots referred to were severed the process of augmentation would begin. As the sun declines in power it is the more important that the elaborative functions of the leaves should not be swamped by a flood of watery sap. By severing gross roots early in October, the current of sap would be cut off or reduced, and the buds in the current year's wood be more highly matured in consequence.

The editorial note, and also some remarks of Mr. Hinds, seem to show a slight misconception of my meaning. I made a distinction between water and food. Perhaps such a distinction cannot be established nor sustained in theory, but practical experience appears to establish the fact that certain roots are chiefly or solely water-carriers, and others mainly or chiefly food providers. Hence I retain my own dictum, that the larger the root the more water it will raise, and also the editorial correction (see p. 521) that a "multitude of fibrous roots form better feeders than simple undivided roots," and which is in exact accord with my own assertion on the same page, that "the fibrous roots formed the most and the best food, and the single and undivided roots the least." This Mr. Hinds also shows, by his case of the two trees referred to at p. 597. I am also in entire accord with Mr. Lee's useful remarks on the same page.

We are in accord, therefore, concerning the efficiency of root-pruning, and also the more apparent causes of that efficiency. The main cause may be formulated thus—the breaking up of the few roots into many, and the substitution of fibrous for fangy roots.

If all this be granted, may we not advance a step further, and, finding that we have a change of root culture, and of top character and produce, assume or prove that we have also a change of root formation—in other words, that the fibrous roots formed food and the fangy ones water? Not but that either set of roots may do either or both in the absence of or in conjunction of either; but that the primary function of the former is to collect food, the latter to carry water.

It seems probable that roots perform a third function, that of changing the character of the food absorbed. If this is so it may readily happen that the altered size, and changed structure of the roots, may materially affect the character of the materials conveyed by them. The larger the roots probably the less changed the materials they convey, the smaller the more changed. We have a striking illustration of this in animal nutrition. It is in the ultimate tissues of the body, where arteries and veins are reduced to mere lines of invisible fineness, that blood is finally converted into animal tissues. May it not, therefore, happen that the matters absorbed from the soil by fine roots should undergo such important changes during their transmission, as to affect the growth and produce of the trees? Besides the reduction of size may also determine to a great extent the election of food. Roots are too often considered mere involuntary channels conveying mechanically, as it were, anything and everything presented to their open mouths or spongioles. They are so, to a great extent, no doubt, as is abundantly proved by daily experience and scientific experiments. But roots are more, and better than mere mechanical tubes. They have either vital power of election or transformation of the most wondrous potency. And it is highly probable that instead of all the elaborating processes of plants being carried on in the leaves only, that certain changes begin to be effected the moment food or water are absorbed. In fact I have long been of opinion that the roots of plants do, at least to some extent, elaborate or digest or change the character of a portion of the

food absorbed by them. If so it is an easy and a material step from this to assume that the finer and more numerous the root channels the more potent their power in this direction, and consequently the better fitted this partially elaborated or more highly refined sap for the establishment and perpetuation of fertility. F.

TIE FOR TREE GUARDS.

WE copy from the *Bulletin d'Arboriculture* the accompanying illustration, fig. 133, representing a very simple and efficient tie for staking trees. They are composed of semi-circular bands of zinc or galvanized iron lined with a thick cushion of plaited Rush, and with wires at the end to tie it in its proper position. The Rush plait does not rot so soon as straw, which is commonly used, does not harbour so many insects, does not injure the tree, and can be more quickly and easily fixed in place than the ordi-

FIG. 133.—BANDS FOR TYING UP TREES.

nary tie. They are made of various sizes by M. J. Durand, Cité des Fleurs, 16, à Batignolle, Paris.

Notices of Books.

Thompson's *Gardener's Assistant*. New edition, revised and extended, by Thomas Moore, F.L.S. London: Blackie & Son.

We hail with the greatest amount of satisfaction the completion and appearance of this new, revised, and greatly enlarged edition of the *Gardener's Assistant*—the best hook on general practical horticulture in the English language. There is no doubt about this. Ever since the appearance of the original edition direct from Thompson's own pen, it has been felt and acknowledged to be a text-book, and the leading authority on the general principles of English gardeniug. There have been many writers on gardening subjects, but no one has conveyed so much direct and correct information on the first principles of the art, or has made it so plain to the common understanding, as Mr. Thompson. This was the great power of Mr. Thompson's writings—they were real; the writer was a perfect master of his subject. It would be a work of supererogation for us, however, to recapitulate all the sterling merits of the original edition; they are well known. A new edition was, however, required to bring it down to the present time, to embrace and introduce all the great advancements and discoveries made in horticulture in the present age, &c., and no man more fitting for the task of preparing it could have been found than the editor, Mr. Thomas Moore.

The quantity of new matter in this edition amounts to nearly one-third of the original work, and a closer type has been employed for the various descriptive lists of trees, flowers, fruits, &c. Many new and additional illustrations have also been introduced into the text. Eight new and beautifully executed coloured plates of new plants and flowers, twenty-four superb engravings of ornamental trees and plants, many plates of horticultural buildings, and, lastly, two most interesting and instructive plates of those insects which are most injurious to vegetation, the whole making a compact handsome volume of over 1000 pages of clear and excellent type.

The editor very carefully distinguishes the new matter from the original. In the preface we are told that "In those matters which relate to the science of gardening and to the practical operations of the vegetable and fruit gardens . . . no further alterations have been made than those rendered necessary by the lapse of time, and those chiefly among the selections of vegetables and of fruits." "It is in the section devoted to the flower garden, which had been unduly compressed for want of space in the original edition, that the greatest change has been made; and in this division of the work the subject is now treated with the fullness which its importance requires." No words of ours can better explain the character of the work before us. There was little room, indeed, for any improvement on Mr. Thompson's writings on the science of gardeniug or the practical operations of the vegetable and fruit departments. His writings on these subjects remain almost for all time. In the flower garden section, however, the original work was extremely weak, while now it is strong. In point of fact a new part has been added to the *Gardener's Assistant*, giving it a new character, a broader basis of usefulness to the gardening world at large.

In those matters which had become susceptible of change through lapse of time in the vegetable and fruit departments, we could almost have wished—only it is something like straining at a gnat where so much that is good has been done—that the editor, who knows so well how to use the pruning knife, had just done a little more; but we imagine his hands have been somewhat tied by the existence of stereotype plates. Hence, the "revised lists" of fruit and vegetables are not quite so thoroughly "revised" as they might have been, a good many sorts of doubtful quality, of doubtful existence, are still retained, but we feel bound to say that no worthless varieties under the guise of "being new" have been introduced.

Several new papers on fruit cultivation appear; that on "Orchard House Culture" being well written and most appropriate. The division entitled "Forcing Fruits and Vegetables," which is still retained, ought to have been merged into the general treatises on the various subjects, and which would have made them more complete. In Thompson's days forcing was a distinct sort of department, but in the present days of cheap glass, glass protectors, orchard-houses, ground viberies, and everything being produced out of season and in season, it is impossible to define "forcing." Besides, under this very heading, "forcing," we are given the "outdoor culture of the Vine," &c.

Of the flower garden section, which is all but entirely new, we can only speak in terms of the most unqualified praise. We turn to the index—well, what is there in it? Everything? Yes!—everything, almost, that does or can concern a flower garden or a lover of plants. We are here given the most full, carefully selected, and thoroughly descriptive lists of plants and flowers that, perhaps, have ever appeared in any one book before, that is, as adapted for the adornment of an English garden; all sorts of plants are noticed, for all sorts of places, and all sorts of purposes. This is one great and special feature of the hook; and we are not only told what to grow, but the instructions as to their cultivation are as copiously and completely given. It is difficult amongst so much that is good to notice any in a special manner. If we say that the articles on the Rose are good, so also are those on hardy herbaceous plants, window gardening, sub-tropical gardening, and floral decorations, &c. We forbear to quote from any, but strongly advise the reader to buy the hook and consult it at leisure. It is a book that ought to be in the hands of every young gardener as a handy-book of guidance and reference on almost all the practical matters relating to a gardener's duties. It is a true *Gardener's Assistant*.

There is, however, one great fault—shall we call

it?—attached to it, a fault that destroyed in a measure the usefulness of the original edition, a fault recognised and oft lamented on to the present writer by good Mr. Thompson himself. It is too expensive—too expensive for the pockets of poorly paid gardeners. It was for gardeners that Mr. Thompson wrote this book, as he very often expressed—to be to them “an assistant,” and it is put beyond their reach by the price being greatly enhanced through the introduction of the coloured plates of flowers, &c., which are of no real practical value. They make it a very handsome volume certainly to those who can afford to pay, but what else? We hope the publishers may see their way to issue an edition, without the plates, in a much cheaper form, condensed perhaps and rearranged, to bring it within the reach of those whom it was originally intended to benefit. *A. F. B.*

—The last number which has reached us of the *Indian Forester* opens with a very valuable paper by Dr. Schlich on the general principles of forest management, by which we mean systematic conservancy, not the mere happy-go-lucky rule-of-thumb business which often stands for woodcraft in this country. Dr. Schlich's paper is based on the best German practice, modified by the peculiar requirements of India, and will probably be extended over several numbers. Colonel Beddome contributes a short note on the forests and flora of the Tinnevely district, alluding among other things to *Podocarpus latifolia*, the only Conifer of Southern India, and one found in some parts of the Himalaya and in Ceylon, but not known in the intermediate district till discovered abundantly in some of the Tinnevely forests at altitudes of 2000 to 4000 feet. The occurrence of a beautiful species of *Cypripedium* is also of great interest, as the genus does not occur elsewhere in the Peninsula or in Ceylon; nor, says the writer, must the beautiful Balsams be excluded from special mention, *Impatiens grandis*, *umbellata* and *uncinata* being all very beautiful plants peculiar to these ghats, and *Impatiens viridiflora* and *aureolata* most curious epiphytic species.

The Villa Garden.

MAKING A FRUIT GARDEN.—This comes as a seasonable topic, for now that the weather is mild and open, and it is fairly dry, or dry enough not to seriously retard outdoor operations, the ground can be prepared, the trees planted and securely staked where necessary, and all made neat and tidy ere the frosty weather puts in an appearance. It may not be far distant from us, for the year is rapidly drawing to a close, and on clear starlight nights there is a sharpness in the air and a glow in the northern sky that presages frost and snow, and as one of the old poets has it—

“The heavens are all coldly clear—

Through leafless boughs the keen winds blow,”

and, therefore, it is time all outdoor planting be hastened on as fast as possible—

“Before the mute snow covers all
The third land as with a pall.”

THE ARRANGEMENT OF THE FRUIT GARDEN.—In the case of a small garden, where space is of some importance, and it is necessary to keep the soil as open as possible, it is perhaps best to make a plantation of pyramid trees, and let it be a permanent one, using Apples, Pears, and Plums for this division of the fruit garden. If the garden be large enough and open enough to allow of some standard trees being planted they should be Cherries and Damsons, and such Apples and Pears as do best in a standard form.

There is this to be said in favour of standard trees, that other crops can be grown under them; but on the other hand pyramid trees can be planted much closer together, and so the advantage in the one case balances that in the other. In addition, pyramid or espalier trees of Apples, Pears, and Plums can be planted in lines by the sides of walks, leaving a 4 or 6 feet border between the trees and the walk. Here space is afforded for cordon trees, and notwithstanding that they have been heartily condemned in some quarters, they are yet cultivated by many, and with a good measure of success. The planting of walls shall be treated of afterwards, at present we have to do with such fruit trees as those above named. In all methods or arrangements of planting, while economy of space is duly considered, let the trees have fair play. It is a common fault to plant too thickly; the Villa gardener likes an immediate effect—he wishes his garden covered, and he settles in his own mind he will have some of the trees removed by-and-by to make room for others; and then, when time has passed, and the crowded trees challenge attention, he finds he has become attached to them as old friends, and is reluctant to thin them out. It is best to plant thinly in the first instance, cropping the space between the trees—in the case of plantations—with vegetable crops, till such time as the trees have covered the ground.

SOIL FOR FRUIT TREES.—Gardeners are accustomed to say that a tree or plant “delights” in a certain soil, meaning thereby that it grows well in it, flourishing vigorously as if perfectly at home. We may, therefore, state with truth that fruit trees delight in a good loam. For assisting the production of fruit on pyramid trees, a good loam resting on a gravelly subsoil is the best; and especially does this remark apply to Pear trees. On a loam resting on a clay bottom, and especially if the clay be at all near the surface, Pear trees on the Quince stock will make a most vigorous growth, root and branch, and this causes them to be some time getting into bearing. Where the clay subsoil prevails it would be as well if a layer of stones or some resisting material could be placed 2 feet or so in depth below where the trees are planted, to prevent the tap-root striking downwards, and at the same time cause the fibrous roots to spread out horizontally, by doing which they are more under the management of the cultivator for root pruning, &c.

If the soil be poor, *i.e.*, if it has been used for the growth of vegetable crops, &c., and there is reason to fear it has become impoverished, a dressing of manure and decayed vegetable refuse may be given, digging it in just where the trees are to be planted, and thoroughly mixing it with the soil. It is best to do this sparingly rather than plentifully, as it is an easy matter to further manure by means of mulching and top-dressing when required.

WHAT TO PLANT.—Let us take the Apple first, and make a selection of suitable sorts in the order in which they will come into bearing. Here are twelve dessert Apples to commence with, all of which are suitable for growing as pyramids, and have been found to succeed in that form:—White Juneating, Red Quarrenden, Yellow Ingestre, King of Pippins, Cox's Orange Pippin, Sykehouse Russet, Ribston Pippin, Fearn's Pippin, Kedleston Pippin, Cockle Pippin, Old Nonpareil, and Sturmer Pippin. Then of kitchen Apples the following are well worthy the attention of Villa gardeners:—Kewick Codlin, Lord Suffield, Beauty of Kent, Blenheim Pippin, Emperor Alexander, Mère de Ménage, Pomeroy Russet, Bedfordshire Foundling, Alfriston, Royal Russet, Norfolk Beaufin, and French Crab.

In getting these trees from a nurseryman they should be asked for as on the Paradise stock. It is a stock on which pyramid Apples are generally worked, because it does not induce an over-vigorous growth, and also because it tends to fruitfulness.

What is known as the “bush” tree was a great favourite Apple tree with the late Mr. Thomas Rivers, and he used to speak of them as “the most delightful trees ever invented.” He regarded them as especially adapted for small gardens, and, as he remarked, “by planting them every artisan and Villa gardener with their suburban gardens may grow their own Apples.” These the late Mr. Rivers always worked on the Nonesuch Paradise stock, and for this reason, that he found it kept pace with the grafts, so that they did not swell over the stock, disturb the health, and shorten the life of the tree.

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—Fern-house.—Ferns that require warmth for their cultivation, and especially when a higher temperature, as is often the case, is given them than necessary, are very much subject to the attacks of two insects—scale and thrips, which are both more difficult to destroy on these plants than on most things, by reason that many species, particularly during the growing season, will not bear an application of tobacco smoke sufficiently strong to kill the thrips, nor any of the solutions employed for the destruction of scale, without destroying or seriously disfiguring the young immature fronds. If by washing and fumigation means were taken for their destruction earlier in the autumn, as soon as growth was completed, these should still be persevered with. Mere killing of the large matured insects is not sufficient, nothing less than complete extermination of the young in all their stages will do away with the necessity of repeating the same process year after year. I frequently meet with collections of *Feros* upon which a great amount of labour is expended in trying to cope with these insects, and still the plants have a frowsy unsatisfactory look, from the fact that brushing, sponging, fumigating, and washing are carried out to an extent sufficient to rob them of the delicate healthy green appearance they ought to have, but not enough to eradicate the insects which are the cause of the mischief. With Ferns of a naturally strong-growing habit, especially the tree kinds, which if allowed a great amount of root-space often outgrow those of a weaker, more delicate character, as well as the room available for them, where they are affected with scale, the under oldest fronds will generally be found the worst infested, and of these there need be no hesitation at cutting away a portion, say up to one-fourth or third of the whole they possess. This will considerably lessen the labour in cleaning them and have the desired effect in reducing the size of the fronds they produce the ensuing summer. In fact I have known experienced cultivators of Ferns resort to this annual cutting away system with plants that were quite clean, the object being to keep the growth within bounds, the fronds at the same time affording acceptable materials for decorative purposes where cut Ferns are required. The fronds of the deciduous *Davallias* may, without doing them any harm, be gradually used for cutting from this time forward until the rhizomes are bare. These, such as *D. bullata* and *D. elegans*, keep well in a cut state. Where large Ferns are wanted for cutting nothing surpasses in appearance or endurance the glaucous-leaved *Cibotium*, *C. Barometz*, and the strong-growing *Adiantum formosum*, for which purpose it seems strange that these two Ferns are not more generally grown, as if plenty of root-room is allowed them, one-half the fronds they produce after the plants have attained a considerable size may be cut during the winter without weakening them. The deciduous *Leucostegias*, as soon as their fronds are dead and fit for removal, must not have nearly so much water given them, otherwise it will have the effect of rotting their root-fibres; but on the other hand it must not be withheld to such an extent as to let the soil get quite dry, or it will destroy or seriously weaken the plants. The atmosphere of the Fern-house should now be kept much drier than during the season of active growth, withholding the use of the syringe altogether where *Gymnogrammas* are grown. These should be removed to a warmer house, as they will not be at so low a temperature as other Ferns; they should not be subjected to much under 60° in the night. This will be found much better than keeping the rest of the collection too hot with a view to accommodating them. From 45° to 50° in the night, with a few degrees' rise by day, is the most suitable temperature to maintain for the general collection for the next eight or ten weeks.

FLOWER FORCING.—*Azalea amœna* is one of the best plants we possess for winter forcing. It affords a distinct and useful colour, and is naturally such a good grower that with fair treatment through the summer, when the plants have attained a moderate size, almost all the flowers they produce may be cut with from half to two-thirds the current season's wood. A few plants at a time should be introduced into heat as required either for cutting or conservatory decoration. *Genistas* also should be similarly dealt with. The old *Acacia armata* and *A. Drummondii* are amongst the best plants for a like purpose, as both may be cut freely with no further effect than its keeping the plants within bounds as to size, which is often rather an advantage than otherwise. In growing forced flowers for winter for cutting, the eligibility for the purpose to a very great extent depends upon the way the plants are treated whilst in heat. We frequently hear people complain that such and such flowers are very nice to look upon whilst on the plant, but they are of little use in a cut state, as they are no sooner severed from

the plant than they begin to wither, whereas with others the same flowers will last for days in an ordinary living room. The cause of the difference is not far to seek; the former are produced with too much heat, too much moisture, and too little light, by being stood whilst the flowers were developing too far away from the glass, often in bottom-heat; the two last causes are the most mischievous. For such things as the foregoing a night temperature of 60°, with 5° higher in the day, and the heads of the plants elevated to within a few inches of the roof-glass, will bring them on into bloom in a way that will enable the flowers to last double the length of time when cut that they will when grown under the opposite conditions. Hyacinths and Narcissus must also be brought on in heat in quantities proportionate with the demand. These likewise are much better not subjected to too high a temperature, and with all the light possible after the advancing tops have got inured to it. *T. Baines.*

ORCHIDS.—The Pleiones which more or less for the last month have been very gay with bloom, will now in most cases be over. On an examination of the bulbs and flower-shoots, which by-the-by are new growths at the same time, it will be found that a number of new roots are just starting away ready to supply the growths with support during the season, which is now commencing with the majority of this class; hence it will be advisable that they should be looked to, and where they have not been potted for a couple of seasons they must be shook out, the greater part of the old soil carefully picked out, the old bulbs cut away, and then without tending them or separating every bulb they should be made up, if sufficient are at hand, in pans of about 10 inches in diameter. That they will bear pulling to pieces like Calanthes, every bulb being pulled apart, roots and old bulbs cut away and thus made up, is at once admitted. I have for a number of years managed them very successfully in this manner, and always been rewarded with fine displays of bloom. I have also grown them in the pans without disturbing them for two years, and in this way they too have grown and produced abundance of bloom. However, since if they are pulled to pieces, each bulb apart, torn from its adjoining neighbour, the roots are much bruised and injured, they do not always so readily start away again. The plan I have found the best, is to shake them out and make them up in clumps, merely pulling the bulbs just apart without separating them, for sometimes they are so well rooted and become so matted together that they can only be parted by cutting through with a knife. When thus kept in clumps the check seems to be much less, and the roots quickly get into work and activity, and instead of the young shoots turning black, as they often do, more especially those of *P. maculata*, caused, doubtless, by too much moisture about them whilst the roots are not sufficiently strong and numerous, the young growths start away with vigour, the leaves assuming a dark green colour, and instead of being so narrow as they are often to be met with, they become rather disposed to be shorter in length, with greater breadth. In making them up the pans must be well crocked, for, being fond of water, when once fairly started into growth it is necessary that the water should pass quickly away; over the cracks place a layer of moss and begin to make the clumps up, using a mixture of Sphagnum moss, fibrous peat, small crocks, and silver-sand; the whole should be well mixed together, and should have been placed in one of the houses or sheds where it may become genially warm before using; keep the bulbs in the centre of the pans, 3 or 4 inches above the rim, filling the others in as the operation progresses. By this means when the flowering season comes round the flowers show to much better advantage than if the bulbs were placed together on the level. *P. humilis* is always later in flowering than the others, and therefore until it has bloomed it must on no account be disturbed. When the pans are made up they should all be stood together in the warmest end of the Cattleya-house, they then can be more easily managed than if spread about in different parts of the stages. *W. Swann, Fallowfield.*

FLOWER GARDEN, ETC.

The season is still favourable for planting trees, shrubs, Roses, &c. Let the ground be well prepared for the latter, and some fresh loam used with each plant as the work proceeds. Chrysanthemums in the flower-borders and shrubberies are now blooming freely and making a very interesting display, which at this season is always desirable. The Christmas Rose (*Helleborus niger*) will soon be showing its welcome and seasonable flowers; if a handglass is put over the plant it will protect it from heavy rains or sharp weather. Laurustinuses are showing great profusion of blossom, but are several weeks later than they usually are. The common Arbutus (Strawberry tree) is also flowering abundantly, but in many places the fruit, which is so showy, is very little more than half its usual size, and not likely to ripen this year; but Holly-berries are plentiful, and will be much prized

when the season is further advanced. When the weather is unfavourable for outdoor operations all bedding plants in houses or pits, especially Pelargoniums, had better be looked over and decayed leaves picked off; any dead pieces of the tips of the shoots which may have been touched by the frost, that in some places came rather sharper than was expected at the time, had better be cut off, and the stock all looked carefully over, as the plants are not so apt to suffer from damp when all decayed matter is cleared away. At this season of the year all bedding stuff with few exceptions will require very little water and will stand frost better when they are kept tolerably dry; pits and frames which are filled with half-hardy and some of the choice varieties of hardy Phloxes, Pentstemons, &c., will be the better for plenty of air on all favourable occasions. Calceolarias if kept from frost will not require much attention until they are rooted and beginning to grow, when air every fine day will keep them strong and prevent them from drawing up. Have protecting material in readiness, for it may be wanted at any time. It is also important to sweep and roll the grass and gravel walks frequently at this season, as they sometimes are apt to be overlooked. Leaves and litter should be removed wherever they accumulate. *T. Blair, Shrubland Park.*

FRUIT HOUSES.

THE CHERRY HOUSE.—If those indispensable preliminary operations which I referred to in the preceding Calendar upon this subject are not yet completed in the early house, let them be finished off without any further delay, and, if not already done, have the surface of the borders in which the roots of the trees exist mulched about 3 inches thick with suitable material which is free from any troublesome insect-pests. If the trees are full of health and vigour the requirements will be to keep the roots near the surface and to protect them from damage and prevent too rapid evaporation. For these objects half-decayed manure will suffice, but if, on the contrary, the trees require stimulating and reinvigorating, then use manure of the best description in a decomposed or pure state, from 2 to 3 inches thick. It will be necessary to close this house very shortly, and to employ the needful means to start the trees if ripe Cherries are required for use at the commencement of next May. This excitement must, however, not be too precipitately enforced if successful results are to be realised; therefore, forcing operations should be commenced at about 40° at night and 50° in the daytime. Open the house slightly at about 55°, and close it up finally for the day at about this point, and allow it under such conditions to range 5° or 10° higher than the natural temperature out-of-doors throughout the day. These temperatures should rule during the next month's proceedings, and with an occasional syringing and sprinkling of the trees and other inside surfaces when they become dry, will be all that is necessary here for the present. *G. T. Miles, Wycombe Abbey.*

CUCUMBERS.—The early winter plants treated as recommended in past Calendars will now be strong and vigorous, and equal to the production of a steady supply of fruit through the dull dark days now upon us. If in pots partly plunged in fermenting Oak leaves the roots will now be finding their way over the sides into the rough turf and rubble round them, and the trellis covered with short-jointed growths bearing thick leathery foliage—a striking contrast to plants which have been forced beyond their strength in close moist pits, where they have been allowed to carry a flush of fruit before the roots have become fairly established. With plants in the above described satisfactory condition when these lines appear the battle may be considered more than half-won, but strict attention must be paid to details, if the seed is to be kept going at a time when it would be most inconvenient for it to stand still. The first care must be the steady maintenance of a bottom-heat of 80° to 85°, which will keep the roots at work and capable of taking up the supplies of tepid liquid manure at a time when it will be of the greatest service to the plants. Top-heat may be regulated by external conditions. When the weather is mild and fine it may range from 68° to 85°, but on cold or wet nights a fall to 65° will do less harm than incessant firing, providing the maximum temperature is approached once within the twenty-four hours, and the bottom-heat is not allowed to decline. If blinds on rollers can be used for running down at night and during snowstorms, a great deal of dry firing will be saved, and the internal temperature, whether high, low, or intermediate be in favour with the grower, will be less liable to sudden depressions so often fatal to winter Cucumbers. By dressing over the plants twice a week, and the frequent removal of a few of the old leaves, surplus fruits, and male blossoms, the young vines, which must not be closely stopped, will keep growing and showing fruit, providing the plants are kept free from insects and over-cropping is avoided. Less moisture will now be required, but the evaporating pans may be kept full,

and an occasional dusting with dry sulphur will keep mildew and red-spider in check. Last, but not least in successful culture, cleanliness must be observed internally by the removal of all decaying vegetable matter, the application of fresh lime-wash to the walls, and externally by an occasional washing of the glass and paint. *W. Coleman.*

HARDY FRUIT GARDEN.

The exceedingly mild weather with which we are now favoured is just the thing for this department of the garden, and should be taken every advantage of to push forward all pruning and thinning necessary for such trees as Apples, Pears, Plums, and Cherries, beginning with the former and following on in the order they are named. I have seen pruning done when those engaged at it could scarcely hold a knife or handle a nail, much less use them in an expeditious or proper manner, and no doubt this has been the experience of many more, when with a little management such a hardship might have been easily avoided. Many persons defer the pruning of bush fruits till quite late in the season, thinking thereby to save them from the attacks of sparrows and other feathered depredators, but where birds are at all troublesome such a course is of little avail, as the chances are that they will strip off most of the buds long before the winter is over. I find that by far the best way is to prune early, and immediately after to syringe the trees over with thin limewash in which some soot has been stirred, and if water is used for mixing that has had some quassia boiled in it it will be the more efficacious, or, what is better still, about half a pint of carbolic soap to every four gallons of the liquid. The lime should be quite fresh and only slaked just before using, and if strained through a fine sieve to take out any lumps there will be no difficulty in putting it on. The best time to apply it is when the bushes are moist with dew, as then it adheres readily if the day sets in fine and favourable after. Besides the great advantage of insuring the safety of the buds, lime acts most beneficially in ridding the trees of all kinds of mossy growth, and rendering the bark clean and healthy, and is therefore desirable on that account. Near towns or farms where sparrows abound, or in mural districts where bullfinches are troublesome, this lime-dressing is the only way to secure a crop of fruit unless netting is resorted to, the expense of which for such a purpose renders its use quite out of the question. As regards Apples, much may be done to increase the size and quality of the fruit by a judicious thinning to let in the sun and air among the branches, and this is a matter that should receive immediate attention, removing all such as cross each other, or that appear in any way misplaced, and can be spared without interfering with the general symmetry of the tree. If this were done annually orchards would be more productive, as, instead of the growth being drawn and weak, it would be short, sturdy and strong, and bristling with fat buds from base to summit. In the case of espaliers, the spurs of which after a few years' pruning become thick and crowded, they may now be thinned out by cutting away or shortening back all such as are not likely to be fruitful, so as to force them to break again lower down, when, after another season, those left now may be served in like manner. The same operation should be carried out with Pears on walls, or such as are grown as pyramids, as by so doing they may be kept nearly close on to the main branches, and this enables the sap to reach the point more freely than is possible with spurs long, twisted, and knotted in the manner one frequently sees them. Independently of this, the blossoms of those on walls are brought much nearer to the bricks, where they are in a better position for shelter, so that when others fall such as these so favourably situated generally escape. In the training or supporting of Pears against walls or buildings I find nothing equal to galvanised iron staples, which when once driven in remain permanent and can readily be made use of to put a piece of tar-twine through at any time required. As they are very neat, and there is no defacing or injury to the joints of bricks in the wall (there is when nails are used, I would strongly recommend them in preference to anything else, except strained wires, which are best for Peaches and Apricots, on account of the young wood that has to be laid in annually; but for dessert Cherries, Plums, and Pears, that have to be grown on the spur system and simply made fast in their places, anything beyond a few staples and an occasional nail and shred is quite unnecessary. It often occurs that during the spring months, if the blossoms of Peaches and Nectarines could but have been retarded for only a few days they would have escaped being cut off by frost, and if the branches are now detached from the wall and tied securely and carefully to poles or stakes sufficiently far away from the bricks not to be affected by the heat they absorb during sunny days, they may be kept back at least a fortnight later, and perhaps by this means a crop of fruit secured. At all events, considering the vicissitudes of spring, the practice is well worth a trial. *F. Shiffara.*

THE

Gardeners' Chronicle.

SATURDAY, DECEMBER 1, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY,	Dec. 3—	Sale of Dutch Bulbs at Stevens' Rooms.
TUESDAY,	Dec. 4	{ Royal Horticultural Society: Meeting of Fruit and Floral Committees at 11 A.M., and Scientific Committee at 1 P.M.
WEDNESDAY,	Dec. 5	{ Sale of Roses, Camellias, Bulbs, &c., at Stevens' Rooms.
THURSDAY,	Dec. 6	{ Meeting of the Linnean Society at 8 P.M. Sale of Orchids at Stevens' Rooms.
SATURDAY,	Dec. 8	{ Sale of Fruit Trees, Shrubs, Plants, Bulbs, &c., at Stevens' Rooms.

THE proceedings at the Mansion House on Monday last will be perused with mingled feelings of disgust and satisfaction—disgust, that such nefarious practices as formed the subject of the trial should still be, or have been, carried on—satisfaction, that the full penalty allowed by the law on a first conviction was duly enforced, the case being clearly proved. In the year 1869, as will be remembered by many readers of this journal, a Bill to prevent the ADULTERATION OF SEEDS was passed through Parliament, chiefly by the energy of Mr. CHARLES SHARPE, supported by most of the leading seedsmen. The Government, and Mr. BRIGHT in particular, who was then head of the Board of Trade, offered no sympathetic assistance to the passing of the Bill, but rather the reverse. Eventually, however, the Bill became law, and was printed in full in the *Gardeners' Chronicle*, 1869, p. 939. Of the necessity for such an Act those who read the evidence given by the seedsmen themselves could have entertained no doubt. The honest seedsman could not maintain himself in the face of ruinous and dishonest competition; the consumer was, of course, defrauded, and remedy was difficult if not unattainable. For some time the Act is believed to have worked well, and to have deterred evil-doers; but lately evidence was obtained of the renewal of these fraudulent practices, and the result was the trial at the Mansion House, elsewhere reported. Owing to the difficulty of detection, and of obtaining evidence strong enough to ensure conviction, it became necessary to appoint an inspector (not provided for by the Act itself), and to enable him to enter into business on his own account as a seedsman. In this distasteful manner at length direct evidence was obtained of the killing of seed, and of the sale of such seed. It became known in one instance that a large quantity of Clover seed and of Alsike Clover had been "milled" in a manner similar to what is alleged to have been practised at Worcester. The good effect of the Act has been illustrated by the fact that since the passing of the Act it has been necessary to be cautious; so that while the enterprising seed-killer could formerly show himself openly in Mark Lane, it was necessary now to wait in the passage at No. 60, or round the corner at the tavern, where those who employed him came and handed delivery orders for any seed they wished "done." Frequent changes of clothes became necessary to avoid inconvenience of ill-timed recognition. So profitable was the business in one case, however, that offers of partnership were, we understand, made, but the proprietor of the business preferred to keep the matter in his own hands and in that of his sons.

In the case which came before the Lord Mayor on Monday last it was shown that the object of killing seed was that it might not grow and betray its worthless character, for were it to grow the farmer would at once know that he had been defrauded, and that that for which he had paid 60s. a bushel, believing it to be Turnip, was actually composed, in some instances, of 50 per cent. of spurious seed. On the other hand, if undiscovered,

the seed would be sown, and its failure would be attributed to natural or unavoidable causes. The difficulty of bringing such fraudulent practices home to the guilty parties, and the honour between "man and man" (saying nothing as to between man and men) are significantly illustrated in the report of the trial. One CHAPMAN, employed as it seems by STRANGEWAYS, produces a sample of "killed Charlock," price 6s. 6d. a bushel. A few days after STRANGEWAYS presented himself to the would-be purchaser (the inspector), and produced an invoice, in which the seed was described as "old Charlock." Witness seeing that, said they must have an understanding together that the seed was not to grow, because if it did, according to that invoice, he had nothing to fall back upon. The defendant "clapped him on the shoulder and said, 'Between man and man not a seed of it would grow, and that if it did he would put it in the kiln again for nothing,' adding, 'you know the state of the law. We cannot put anything into writing, but you must trust me and keep your own counsel.'" In a subsequent conversation STRANGEWAYS is reported in court to have said, "You can depend upon the seed being thoroughly well done, and not like FRITH'S. They shoot down the seed in the kilns, but don't scrape the sacks. I am very careful with this seed, and I always scrape the seams of the sacks myself with a small needle, so that there cannot possibly be a single seed to grow."

The defendant's counsel did not offer any defence or extenuation of this rascality, but recommended his client to withdraw his plea of Not Guilty, which was done, and the defendant mulcted in the full penalty, with costs to the amount of five guineas—a trifling matter as regards the immediate pecuniary loss, but sufficient, we hope, with the attendant publicity, to prevent any more sack-scraping for some time to come.

While congratulating Mr. SHARPE and those who acted with him on the successful result of their labours, we may express our regret that so invidious and difficult a task should be left to private individuals. Failing a public prosecutor the Royal Horticultural or Royal Agricultural Societies should take up such cases when assured of their validity. The Royal Horticultural Society, we know, is not burdened with funds to undertake such duties, while it is not the first time that the Royal Agricultural Society has failed to do the duty it might naturally have been expected to fulfil. Lastly, a word of caution may be necessary to purchasers. It is to be feared that Swede Turnip seed, which is likely to be high in price, will be adulterated with this dead seed and a revival of the famous ooo ensue, if the present action do not happily suffice to prevent it. We are unfortunately not able to name the London houses stated to have been supplied with dead seeds, but we trust the recent exposure will show them the folly and wickedness of carrying on business in such "strangeways."

The proceedings at the Mansion House had reference to the adulteration of Turnip seeds, and we are informed that summonses are about to be issued against some adulterators of Clover seeds, when startling disclosures may be looked for. No time will be lost in bringing the matter before the Courts, in order to stop the sale, if possible, of large quantities of inferior descriptions of Clover and other seeds which have been prepared for the coming season.

— THE remarkable group of *CYPRIPEDIUM SPECTABILE*, illustrated in fig. 134, is one which flowered in June last in the Birmingham Botanic Gardens, under the care of Mr. LATHAM. The group consists of twelve plants, one of which bore thirty flowers, each very large as compared with the blooms usually seen, and borne in pairs, and in many

instances with three blooms on each shoot. The plants were received in a dormant state from Canada the previous autumn, through J. B. GOODE, Esq. They were potted into good fibrous peat, and kept in a cold frame, and very little water given to them until they began growing, when water was applied copiously, and were kept in this frame until they came into flower, when they were removed into the conservatory. Some of the leaves measured 5 inches long and 4 inches in breadth, and the whole of the plants were in magnificent health.

— We have received copies of the schedule of the tenth (quinquennial) INTERNATIONAL HORTICULTURAL EXHIBITION to be held at GHEENT from March 31 to April 7 next. The schedule is very full and complete, and comprises upwards of three hundred classes, in each of which two, and in most instances three, prizes are offered. Many of our readers well know that the citizens of Ghent are adepts in the art of organising a first-class show, and they know also how cordial and hospitable is the reception given to Englishmen on these occasions. A few copies of the programme are in our hands for distribution, and others may be obtained from the Secretary of the Société Royale d'Agriculture et de Botanique of Ghent.

— Some PEACH ROOTS have lately been forwarded to us in a very curious condition. The surface is swollen more or less through the whole length into rude, unsightly warty knots, while, in addition to the usual fibres, a single long smooth root is given off, which in its turn yields a few delicate root-threads. The affection is common to all the Peaches and Nectarines on the same wall. The border was trenced two years ago, and the roots cut within 2 feet of the trees. As far as we can judge, the long roots in question, which at present are perfectly even, were the consequence of the root-pruning. It is quite clear that the knots arise from a tendency to throw out numberless adventitious buds or suckers from the same spot; that these suckers are never fully developed, that they die back and thus form a sort of canker. It is precisely the same thing which occurs occasionally in Apple trees, as, for example, in the Keswick Codlin, where at last a formidable canker is developed, affecting all the tissues beneath it. It is impossible, without examination of the especial locality, to say what may have produced this tendency; nor have we any information as to its effect on the general health of the trees. It is, however, always a point gained in these kind of questions, to ascertain exactly what is the nature of the affection. *M. J. B.* [We could find no trace of insects or fungus. Eds.]

— At a meeting of resident members of CAMBRIDGE UNIVERSITY, held at Christ's College last week, the Master of Christ's College presiding, it was resolved, upon the proposition of Professor HUMPHREY, seconded by Professor FAWCETT, that a MEMORIAL to Mr. DARWIN should be instituted in the University of which he is so distinguished a member, and which should assume a personal form; and it was understood that it should be a portrait—either a bust or a picture. A committee, with power to add to their number, was appointed, and a subscription started in the room.

— We have received from Messrs. SPEAR & JACKSON, Etna Works, Sheffield, two sets of ANDREW'S PATENT PAXTON GARDEN TOOLS, which they have just brought out. Each set consists of a spade, fork, drag hoe, and rake; and each instrument is made out of one solid piece of steel, and is altogether weldless—an important innovation, which, combined with the efficient principle upon which it is made, should impart the cardinal features of strength and durability. In the spade and fork the iron strap with which the hand in the ordinary tools comes in contact is abolished, and a smooth handle more agreeable to the hand is substituted. The cofer and rivets of the face of ordinary spades and shovels are dispensed with, and a smooth and level surface secured, for which it is claimed as an advantage that it prevents all accumulation of dirt, works easier and keeps more cleanly. Whether, however, the thin layer of wood will not be liable to split seems open to question. The manufacturers also claim as an advantage in the "Paxton" spades and forks that, being divested of the iron straps and shaft at the neck, they will penetrate the earth deeper and with greater ease, and

as there is no clogging of the earth at this essential part, the work of digging is accomplished with greater facility and less labour. The tools included in one of the sets before us are very neatly and well finished off, and intended for the use of amateurs, and the other of good plain finish for gardeners, but both are of the same quality of metal and make, and appear to be exceedingly good. If there is a fault to be found in them, it is in connection with the spades, which are heavier than they need be. We shall give them a trial, and allude to them again if need be.

— The IMPROVEMENT FOUND IN THE CHINESE PRIMROSE, in the way of obtaining intensity of colour, is well illustrated in a house of Primulas at the

exhibitions were rare and of great importance to horticulturists in those days. Mr. BEADON'S name was well known throughout Hampshire, and further as an earnest patron of horticulture, and with a thorough love for plants, as well as possessing a good knowledge of them, and this affection he has retained to the present time. In his library at North Stoneham is to be found a valuable collection of horticultural works, many of them very rare, and it is not long since that, in talking over with a friend, like himself a keen lover of plants, Mr. BEADON referred to one of the books in order to refresh his memory as to the name of the plant he was speaking about. In the rectory gardens many examples of rare trees, shrubs and herbaceous plants are to be found, as well

It may not be altogether new or original, but it obviates some of the disadvantages of the practice of thrusting down a light, putting in the fumigating vessel, and getting half choked with smoke in doing so. This contrivance consists in building a small chamber, a foot or so square, in the bed of the frame, and immediately under the wooden shelves on which the pots stand, which is covered on the top inside with a slate removable at will; access can be had to the chamber outside by means of a sliding shutter, which when closely shut down prevents the draught from passing into the frame. The fumigating pot is put into the chamber, the slate at the top removed, and the smoke finds its way among the occupants of the frame. The chamber is also useful for giving air in very wet and stormy

FIG. 134.—*CYPRIPEDIUM SPECTABILE*, AS FLOWERED IN THE BIRMINGHAM BOTANIC GARDEN.

London Road Nurseries of Messrs. SUTTON & SONS, Reading. A selection of a remarkably high coloured type was made by Mr. MARTIN, the foreman, a year or two ago, and the progeny raised from it, and now flowering, has a very rich glow of colour, and the habit of growth is quite in keeping with the splendour of the flowers, which are also large, stout, and handsomely fringed.

— On Thursday next, December 6, the Rev. Canon BEADON, rector of North Stoneham, near Southampton, will have reached the completion of his hundredth year, having been born December 6, 1777. There are still a few who can remember the Rev. FREDERICK BEADON as an early exhibitor at the Southampton and Winchester horticultural exhibitions of nearly half a century since, when such

as some veteran Camellias against a south wall, and a fine old *Azalea indica alba*, out-of-doors, in the American garden, which rarely, if ever, misses having a good head of flowers. There has always been a good collection of indoor plants, including a nice lot of Orchids, and up to the past summer the rectory plants could be depended upon as a great feature at the local horticultural show. Many a hearty congratulation will be offered on Thursday next to the venerable and much loved servant of CHRIST and the warm friend of all who know him, for he truly "loves to do good by stealth," and at North Stoneham he lives in the hearts of all.

— An excellent contrivance for FUMIGATING PLANTS in ordinary frames can be seen at Messrs. SUTTON & SONS' London Road Nurseries, Reading.

weather, when it is scarcely safe to raise the lights. The beautifully healthy condition of a collection of herbaceous *Calceolarias* filling a long range of frames, their robust growth and fine leaf development, seem to illustrate the usefulness of this contrivance, as they certainly do the painstaking cultural oversight bestowed on the plants.

— The beauty of the JAPANESE CHRYSANTHEMUMS, their brilliant colours and varied form, have been strikingly effective this autumn, and it is worthy of note that they have generally bloomed early, while the earlier flowering incurved types have been quite late. Of the newer Japanese varieties, the following may be said to have made a place for themselves in collections:—Diamond, bronzy chocolate with golden orange centre, large double flowers, and partially

twisted petals; Peter the Great, pale yellow, the flowers large in size, and very striking in appearance; Red Gauntlet, dark crimson, a fine hue of colour, particularly striking in appearance; Sarina, delicate pink or pinkish lilac, a very distinct and taking variety; Magnum Bonum, clear lilac, very fine; Mr. Barnes, clear deep buttercup-yellow, extra fine quality; Emperor of China, white, deepening to bluish with age; Bronze Dragon, very fine; Fulgare, pinkish lilac, very bright and effective, and distinct in character; Baron de Brailly, clear delicate rose, very good; Soleil Levant, clear yellow; and Royal Soleil, crimson burnished with orange, fine and effective. Of the older varieties no collection would be complete without Comtesse de Beauregard, Criterion, Elaine, Fair Maid of Guernsey, Garnet, Grandiflora, Golden Dragon, James Salter, M. Charles Hubert Purple King, Plantagenet, Red Dragon, The Cosack, and The Daimio.

— The exhibitions of the READING HORTICULTURAL SOCIETY in 1878 have been fixed for the following dates:—Spring show, Thursday, May 23; the summer show, Thursday, August 22. As is usual, the exhibitions will take place in the Abbey Ruins.

— At the last meeting of the LINNEAN SOCIETY Dr. H. TRIMEN exhibited specimens of the OLIBANUM or FRANKINCENSE TREE (*Boswellia Carteri*, Birdw.), gathered in October last by Mr. J. COLLINS from the trees planted at Aden, and the same referred to by Dr. S. BIRDWOOD in his paper on this genus (*Trans. Linn. Soc.*, vol. xxvii., 1870). Dr. TRIMEN, in making some remarks on the variability of the foliage of the species of *Boswellia*, expressed the opinion that the *B. Bhan-Dajania*, Birdw., was not specifically separable from *B. Carteri*. The *B. Frereana*, which yields the fragrant resin called Luban Metyi," and which HANBURY considered to be the African Elemi, is much chewed by Orientals, but rarely is imported into England. It is confined in a wild state to the Somaliland, where specimens have recently been collected by HILDEBRANDT.

— For blooming at this season of the year in a cold greenhouse *ARALIA SIEBOLDI* is well worthy attention. It is now in full bloom, and if not particularly striking, the large-branched head of bloom is very interesting, resembling that of the Ivy, but milk-white in colour. While the weather is warm and sunny the balls of flowers will expand, but cold and dull weather prevents its doing this. It is curious to notice how the blow-flies are attracted to the flowers when the sun shines out warmly; they appear to come forth out of their winter quarters seeking the sweet secretion that exudes from the blossoms. Quite a small plant will throw a head of bloom of large size.

— We are requested to state that there will be an international show of BREEDING STOCK in conjunction with the UNIVERSAL EXHIBITION AT PARIS in 1878. Very handsome prizes will be given, viz., from 1000 francs and downwards for bulls, cows, heifers, &c., of the leading breeds of the United Kingdom:—Short-horns, Herefords, Devons, Sussex, Channel Islands, Ayrshire, Polled Angus, Suffolk, Aberdeen, Galway, Scotch, Highland, Kerry, &c. For sheep 500 francs and downwards, for rams, pens of three ewes of the following breeds:—Merino, Southdown, Shropshire, Leicester, Romney, Lincoln, Cotswold, Cheviot, Blackfaced, &c. For pigs, boars, sows, &c. For poultry, pigeons, rabbits, &c. A work of art, for the best group in each division of the show, value 2500 francs; the same for sheep, value 1500 francs; pigs, 1000 francs. Programmes and entry forms can be obtained on application to P. CUNLIFFE OWEN, Esq., C.B., Secretary of the Royal Commission, Canada Buildings, King Street, Westminster, S.W. Intending exhibitors should make their entries by December 20th. The general superintendence of the Agricultural Department has been entrusted to Mr. BRANDRETH GIBBS.

— A strong plant of the climbing *TROPEOLUM PERFECTION* has been for several months trained to the wires at one end of the early Peach-house at Heckfield, and is producing flowers of the richest crimson-scarlet hue and of the most perfect form, in great abundance. The flowers are borne on stems about 4 inches in length, and because of their intense

hue of colour are most valuable for vase or epergne decoration at a period of the year when rich colours are scarce. It is a very robust kind, and is valuable in the open air in summer as in the house in winter.

— The desirability of occasionally examining the state of the butts of large ELM TREES was exemplified at Highfield Park, Heckfield, during a recent gale. A giant tree stood near to the coach road, on one side of which was a fine bank of evergreen shrubs that shut the old church that stands close by from the view. The attention of the Lord of the Manor had been personally drawn to the tree, but it was not thought to be in a dangerous state. During the prevalence of the next gale of wind it blew down, fortunately in a direction to do little mischief; but it fallen to the east it would have smashed in the shrubs and a part of the church, and done great damage. When fallen it was found that, with the exception of about an inch or so of the external wood, all the remainder at the base was quite rotten.

— A very INTERESTING CROSS IN THE TOMATO has been effected by Mr. DAVIDSON, gr. to Mrs. MARSON, of Highfield Park, Heckfield, the seed-parent being the Red Currant, and the pollen-parent Hathaway's Excelsior. The result is much more robust habit; plants still full of fruit on a south wall, and protected at night by mats, are 7 feet in height, whilst the bunches of fruit are much larger, and the fruit at least three times as large as that of the Currant. It is quite distinct from the known Grape Tomato, and is exceedingly ornamental.

— A large breadth of VEITCH'S NEW WINTER-PROTECTING BROCCOLI, now growing in the kitchen garden at Heckfield Place, presents a capital example of the great value of this fine kind as an early winter variety. It make a good succession to the Autumn Giant Cauliflower, turning-in at the end of November, and will probably continue to furnish a supply for a couple of months. The breadth is marked by singular evenness and truthfulness to character, whilst its protecting character is seen in the fact that the leaves entirely cover and enclose the head of flower. It is a really genuine novelty, that is worthy of all praise and wide cultivation.

— The promise made in the spring that the then remarkable bloom upon the HOLLY would be productive of a fine crop of BERRIES has been well fulfilled, as the Holly trees in all directions are covered with rich bright scarlet fruit, masses of which will presently be found making glad the heart of man at the merry Christmas time. It is not worth discussing how far this abundance of berries may prognosticate a hard winter, as that is not worthy of much consideration. It would be more useful to ascertain, if possible, why it is that now and again we get such grand crops of berries, and specially why it is that we find some trees producing a great crop of fruit whilst others close by have not a berry. Some trees are male and others female, and some trees produce a good crop of berries and then rest a year or two whilst their fellows are prolific? One thing is noticeable, that in a large plantation of Hollies the oldest and most stunted trees have the largest crops of fruit. From this it would be fair to gather that the barren ones are expending all their strength in the production of wood, and none in the production of berries. It also often happens that in the great demand for berried Holly heads and large branches of trees are cut off, and as a result a strong robust growth follows which it takes several years to reduce into a proper fruiting condition. It often happens also that where there is a prospective promise of fruit, a late spring frost cuts it all off, and the trees thus get the credit of being males. That some are of that gender is true, but the majority of the wild Holly trees evidently belong to the gentler and more fruitful sex. It must, however, be borne in mind that Hollies, like many other flowers, may be structurally two-sexed and yet functionally of one sex only.

— According to a correspondent in the *Gartenflora* writing from Tiflis, the splendid HARVEST PROSPECTS of that region were suddenly dissipated by terrific hailstorms on the 3d and 4th of June. The hail fell over an area of about 130 miles long, and from 2 to 10 miles broad. In the neighbourhood of the

town of Tiflis the stones were spherical, and from a Hazelnut to a Walnut in size, but along the Vera River they were much larger, and the damage they caused was very serious. Irregularly-formed, sharp-edged stones were picked up, the heaviest weighing 2½ lb. (!) At the colony of Marienfeld, sixty bullocks, numerous horses, and two stags were slain by these formidable hailstones, and the corn and fruit crops of this part completely annihilated. The greater part of the windows in Tiflis were broken, and in the botanic garden alone about 4600 panes. There was not sufficient glass in the country to repair the damage. The garden of the Acclimatisation Society at the north end of the town escaped almost unharmed. Many people were drowned in the streets, or carried by the raging streams of water from the mountains into the open cesspools of the town, there to meet a miserable death. The torrents of rain and hail caused an amount of destruction fearful to contemplate. We grumble very often at the "detestable" climate of our own country, but hailstones as big as brickbats are happily unknown to us. Such a storm would make short work of the Crystal Palace, and the thousands and thousands of glasshouses all over the country.

— The Society of Apothecaries have decided to offer two PRIZES for competition by young WOMEN, under twenty years of age, in THE SCIENCE OF BOTANY. The prizes will consist of a gold medal, and a silver medal and books, to be awarded to the first and second candidates respectively in order of merit. The Rev. M. J. BERKELEY, the examiner for the prizes given by the Society to medical students, will conduct the examinations.

— We are informed that the well-known nursery and seed business so long carried on by Mr. EDWARD TAYLOR, of Malton, Yorkshire, has been purchased by Mr. ROBERT BLACK, lately with the Lawson Seed and Nursery Company, who intends to carry on the business in all its branches.

— The COTTON INDUSTRY IN BRAZIL seems to be largely on the increase, judging from a recent report on the subject. Many large factories are now in full working order in the neighbourhood of São Paulo. In some the machinery has been supplied by the most celebrated English firms. Two great advantages attend the establishment of looms in Brazil—first, on account of the raw material being produced or purchased almost at the door; and next, on account of the large internal consumption of the coarse kind of cloth turned out by these factories.

— A new kind of cultural industry, namely, the GROWTH OF BANANAS, has increased to a considerable extent in Panama during the last two years. These fruits are grown almost exclusively for the New York market. A large tract of land bordering the railway, about a mile from Colon, has been put under this cultivation by an enterprising German, and from this plantation as much as 12,000 tons of fruit are exported monthly to New York, where they sell readily at an enormous profit; the wet, rich alluvial soil of the Isthmus being peculiarly adapted to the production both in quantity and quality.

— The CULTIVATION OF COCOA (*Theobroma Cacao*) in SURINAM, and its exportation, has during the last five or six years increased considerably. Of all the products of the colony it is considered not only the safest, but the most profitable—more so even than sugar—the Cocoa grounds having none of the difficulties to contend with that the sugar estates have. In four or five years after planting the Cocoa tree begins to bear to a moderate extent, and in the eighth or ninth year it attains its full bearing, and continues very productive for about forty years. Its subsequent culture is very simple, and the planter has no fear for the future. A profitable Cocoa plantation of 300 acres can be kept up with a staff of from thirty to thirty-five labourers. The dark and dense shade created by the umbrageous mass of its own foliage prevents to a great extent the growth of weeds, so that it is found unnecessary to hoe the ground, in lieu of which about two clearings with the cutlass are made annually; besides, the leaves of the Cocoa fall in great quantities, forming quite a layer on the ground, and so, by covering, help to exterminate the weeds. In the plucking seasons no difficulty is

found in obtaining labour, as it is said the natives find the work easy, and are paid so much per pound as the seeds are brought in, earning from 2s. to 3s. per day.

— Mr. JOHN MCINTYRE, late gardener to A. A. RICHARDSON, Esq., Aberdelghy, Lisburn, Ireland, has succeeded Mr. JOHNSTONE as gardener to Captain MAXWELL, at Terregles, Dumfriesshire.

— RICHARDIA ÆTHIOPICA is largely grown in some of the market nurseries round London, and it is scarcely necessary to say they are finely grown. Some growers have from 2000 to 3000 plants, in 48 or 32-sized pots according to the size of the roots. A succession is kept up by means of the young offshoots thrown up by the large plants; these are taken off and put into large pots and boxes as stores, and in the spring all that are large enough are potted and stood out-of-doors with a covering of 4 inches of rotten dung over them. An abundance of water is given in summer, as often as three times a-day when the weather is hot and dry. At the end of the summer they are taken into houses and get into bloom by Christmas, at which time the large white trumpet-shaped flowers are in great demand.

— We note that the Messrs. STEVENS & WILLIAMS, Brierly Hill Glassworks, Staffordshire, have now brought out their handsome new registered Hyacinth glasses, illustrated in our columns at p. 319, in various colours. They are very ornamental.

Home Correspondence.

The New Waterproof Card Labels.—In your last impression you refer to our waterproof card and other horticultural labels in a paragraph on p. 659. We regret to inform you that a serious injustice has unintentionally been done to these labels by your statement that they last about eight months, and your reference to a patent indelible ink. This is an entire misrepresentation, and we are sure you will gladly put the matter right in justice to us, and with benefit to your readers. From actual experience we beg to state that these labels will last vastly longer than eight months, and we have no hesitation in saying that it is our firm conviction that they will endure for eight years as well as for eight months. No special ink is required, though probably experience will prove that some of the inks now in commerce are more adapted for the purpose than others. The card which forms these labels is practically imperishable, as well as absolutely insoluble. *The Patent Waterproof Paper and Fibre Company, Canal Works, Willenden Junction, N.W.* [We have subjected these labels to severe tests since our paragraph was written, and with very satisfactory results. They will be a great boon. Eds.]

Tuberoses.—The following may interest some of your readers who are in quest of sweet-scented flowers in winter. A correspondent in France sends us a sample of Tuberoses, the crop of 1876, which were kept during the summer in an open but covered shed. They were perfectly sound, and the writer goes on to observe, "Some of these roots were planted in a small hot-house last September, and are now in full bloom;" and he thinks that such bulbs planted in October could be had in flower at Christmas, and he is desirous of knowing whether any English cultivators have similar experience. It is his intention to follow up the experiment next year, and advises that the plan should be generally adopted. I am sorry that none of your correspondents have given more detailed cultural directions for the management of the Tuberoses, as there is no doubt that many of them go blind for want of proper handling. *P. Barr.*

Ageratum at Castle Kennedy.—A short notice appeared a few weeks ago in the *Gardeners' Chronicle* of some of the seedling Ageratum which have lately been raised here, with a request for further information on the subject. As they have been very much admired during the last two or three summers, and have attracted a good deal of the attention of lovers of flower gardening, I have much pleasure in complying

with the request. A few years ago it occurred to me that the Ageratum possessed many qualities, which, if properly developed, would bring it to the front as a bedding plant; evidently it had not had that attention bestowed on its improvement which its merits deserved; I resolved to try what could be done with it. After procuring a few packages of the best seed I could get, I sowed it, and raised a large number of seedlings, which were very disappointing, scarcely one was worth keeping; very late in the season I discovered one which was a decided improvement, and which was afterwards named Countess of Stair, and was sent out a few years ago by Mr. Williams, of London. The principal step in advance made by this batch of seedlings was variety of colour; seed was saved from the best varieties, taking into account colour, habit, and constitution. For a number of years the same process has been going on, and the result is highly satisfactory; we have now got almost every shade of blue, not a few approaching pure white, others white with red buds, the flowers tipped with pink and other shades of red, some flesh-coloured; a scarlet is within the range of probability. We have now a few varieties possessing all the requisites of first-class bedding plants—abundant flowers, striking colours, strong constitutions, compact and moderately dwarf habit, and as easy kept over the winter as Pelargoniums. We test the best varieties by growing them in beds and lines. Those which attracted most attention last season were—Lady Jane (sent out by Mr. Williams last spring), blue colour, 12 to 16 inches in height, abundant flowerer and free grower, with fine constitution; Beauty, fine dwarf nearly white variety, a pretty distinct bedder, from 8 to 10 inches in height, comes early into flower, has a strong constitution, and is easily wintered; Cupid, the finest of all the dwarf blues, splendid bedder, compact habit, from 6 to 8 inches in height, comes early into flower, strong constitution, and consequently easily wintered. *A. Fowler.*

Cucumbers and Broccoli: a Suggestion.—I have for some time past noticed small paragraphs in your columns on the Telegraph and other varieties of Cucumbers. I will, therefore, ask Cucumber growers to exhibit them at the forthcoming meeting of the Fruit and Vegetable Committee on December 4. It would be a fitting wind-up for the year's labours of the committee. The different varieties of that much-esteemed vegetable, the Winter Broccoli, would also make a most interesting exhibition, and would show, without doubt, which are the best varieties to grow. *R. Gilbert, Burghley.*

Pavia macrostachya (p. 653).—I fully endorse all that you say in praise of this fine shrub, so admirably represented in your large woodcut. But are you correct in speaking of it as a tree? [A slip of the pen.] I have one here which must be at least forty years old, and is every summer a mass of beautiful flowers, but it has always been a bush, never exceeding 3 or 10 feet in height. *H. N. Ellacombe, Bilton Vicarage.*

Covering Early Vine Borders.—Your correspondent "D. M." appears to forget that in starting an early vine, and for some time afterwards, the heat of the house and that of the border outside bear the same relative proportion to the natural ground and open air during the spring. How does he account for the rapid start vegetation makes after a few hot days, and a genial shower or two? Certainly neither of these can have done anything to raise the temperature of the soil to a sufficient depth for the roots to feel it, and yet the buds burst and the sap immediately flows with redoubled force. Take some parts of the north of Europe, where they jump at once from winter to summer, and what about the warmth of soil there and its effect in producing root-action, and is it not rather brought about in response to atmospheric influence alone? If this is the case, then there is no need for the application of bottom-heat to Vine borders, for by simply raising the temperature of the house we do all that is required to set sap in motion. To keep out frost is only following Nature in her course, as she scatters leaves and other material on the ground to protect the roots when they are no longer of service on the branches, and if we imitate her in this matter we shall do much better than by piling a mass of fermenting material where its utility is at least but questionable at any time, and is positively injurious before Vines get into leaf. If this is done, as I before observed, sap is set in motion only to return again to the border, and of this any one may satisfy themselves by plunging a Vine in heat in a broken pot, so that a portion of the front roots are left open to view, and they will soon see that the sap does not remain in the rod pushing at the buds as they fondly imagined. The subject is one of great importance, and I trust will meet with the consideration it deserves. *S. W.*

— May I ask your correspondents "S. W." and "G.," who profess to grow early Grapes successfully without the aid of fermenting materials, and the roots

of the Vines all outside, what the temperature of their borders is from the time the Vines are started till the Grapes are ripe?—the daily readings if possible, or, if not, the weekly "means." If they have not kept an account of these hitherto, will they do so and publish the same next spring, and confer thereby a real service on your readers? Will "G." also inform us what he considers fermenting materials to mean, as it is clear he does not think a "good covering of leaves," protected by straw, comes under the head. Most people look upon them as being among the best fermenting or "heating materials" they can use, particularly for Vine borders? Then we shall be able to judge how far the practice of your correspondents differs from other people's. My experience is entirely in accord with that of your Dunrobin correspondent, who has demonstrated that while the temperature of the vine is ascending that of the border is on the decline, and just at the lowest point when it ought to be at the highest—that is, when the border is unprotected. If this is rational Vine culture it is something new, but it is what "S. W." and "G." practically recommend. At least they are committed to prove, either that they can maintain the temperature of their outside Vine borders at the necessary degree without the aid of fermenting materials, or that the Vine can be cultivated successfully with its top in a stove-heat and its roots in a winter temperature. I think that if anything "D. M." has understated the difference between the root and top temperatures. If we say the mean temperature of the vine is 70° during the months that the Vines are swelling and ripening their fruit, the temperature of the border will be nearly 25° or 30° lower under a covering of non-conducting materials only, supposing it to subside to 40° or 45°; for it must be remembered that, if such materials prevent the escape of heat from the border, they also shut out the sun-heat in March and April, about which period the temperature of the border reaches its lowest point. A Vine border here which was covered early in October with about 6 inches of leaves topped with straw stands just now (November 27) at 49° 1 foot below the surface, and the weather has up to this date been exceedingly mild. By December it will decline to 40° or thereabout, and it will stand at that figure for the next five months if it gets no more assistance in the shape of fermenting materials. It is such facts as these that lead me to ask for more authentic particulars from "S. W." and "G.," and it is incumbent upon them to furnish them if they do not wish to mislead. *S. W. the Second.*

— During the last twelve months, and more especially within the last three or four weeks, a great deal has been written against the practice of covering early Vine borders (see pp. 598 and 662), and why? Now I am, like other gardeners, no advocate for giving heat or protection to subjects not requiring them, and thus unnecessarily wasting both labour and material, of which commodities few gardeners have enough, to say nothing of labour to spare. But some of the correspondents of the *Gardeners' Chronicle* seem to think that it is not only a waste of labour and material, but that the covering of early Vine borders is of no practical use whatever: rather a bold assertion this. I have been, and am still, under the impression that by putting on the early Vine borders a good covering of dung and leaves in autumn that the heat imparted to the border during summer is to a certain extent retained, and not only that, but the heat, little though it be, contained in the covering material will induce the roots to move in an upward direction, when they will not only permeate the 2 or 3 inches of top dressing put on in the autumn, but in some cases the 3 inches of short dung immediately over the soil, to their advantage. That the above is substantially true I can vouch from the fact that in removing the covering of the border, which we do by "halves," the second half never being removed before the Grapes have thoroughly "finished," we invariably find the roots as above described—"a network." Having stated the above simple facts, I will now ask your correspondents "S. W." &c., whether they would consider the state of an early Vine border such as I have endeavoured to describe satisfactory? Perhaps it may not be out of place here to state that we commence cutting Grapes in our first house from the middle of March to the end, but always in March. One of your correspondents speaks of the "enormous heaps of fermenting materials," and the piling of "huge hotbeds," and wonders why it is that they "endure it in the way they do year after year." I have never yet seen huge hotbeds piled on Vine borders, but I have seen as much as 2 feet thick of long dung and leaves (the latter preponderating) put on an early Vine border. Perhaps "S. W." will kindly inform us whether it is the continual early forcing of the Vines or the "huge hotbeds" over their roots that causes them to show signs of exhaustion or debility. According to my thinking it seems but reasonable to put a warm covering on early forced Vine borders, thereby compensating them to a certain extent for that which they would possess if they were not forced—a warm

surface from the sun's rays, which surface I would venture to say would be as hot 3 inches from the surface in the month of April as it would be the same depth from surface under the "huge hotbeds" in November. Does it follow that when the heat in a "huge hotbed" is at 150° that the surface of the soil would be the same? I think that the soil 3 inches below the surface would not be much more than half that, if so much. I do not believe a "hotbed" imparts much heat to a Vine border or any other border. Does not the heat spend itself in an upward direction? That being so, what danger is there of burning the roots of the Vines when they would have received 2 or 3 inches thick of top-dressing and the same of short dung? In conclusion, I humbly contend that the only function—and a very important one it is too—that the dung and leaves perform, is that they cause the roots of the Vines to push upward to the heated surface, where they will find something for their trouble, and with consequent results to the appearance and condition of the Vines inside. Of course your readers will understand that I am open to conviction, and have hastily written these few notes on the spur of the moment, in the hope that some of our leaders in Grape culture will more fully enlighten us on this vexata questio. *H. W. Ward, Longford Castle.*

Aponogeton distachyon.—I was pleased to see in the last issue of the *Gardeners' Chronicle* attention called to this neglected but grand old winter-flowering aquatic, which only requires to be more widely known to be appreciated. The plant is quite hardy in Cornwall, where it grows vigorously, and flowers most profusely in many places. Fine examples of it may be seen at Porthgidden, near Truro, the seat of the Rev. T. Philpotts, but the finest mass I ever saw is at Bodrean, the seat of Arthur Williams, Esq. In its season, there may be seen hundreds of these exquisite wax-like flowers expanded at one time; it is growing in a large pond (which is fed by a stream of fresh water, which is indispensable for the well-doing of this plant). Its valuableness for furnishing cut flowers at this time of the year is only known to those who possess it, and to those who do not possess it it is to be highly recommended. It possesses a most agreeable Hawthorn scent, and keeps a long time after being cut. *S. G.*

—In your last week's issue you bring to notice one of the most beautiful aquatic plants grown out-of-doors in the British isles—*Aponogeton distachyon*. In addition to the places mentioned by you, allow me to say that it does remarkably well in a pond in the grounds of the Rev. T. Philpotts, Porthgidden, Cornwall; it is extensively used for church and other decoration, for which its purity of colour, sweet scent, and lasting qualities eminently adapt it. I have often felt surprised at its being so little known, and had come to the conclusion that it might not be hardy enough to withstand the winters of less favoured counties than Cornwall, but your notice of it so far north as Edinburgh goes far to dispel my fears on that score, although undoubtedly it was assisted to withstand frosts by the ponds being fed by springs. *John C. Tallack, Gloucester.*

—It is gratifying to see attention called to the above very charming plant, which presents many desirable and attractive qualities, and might be introduced to ornament many a corner, particularly where a supply of water is at command. It is perfectly hardy, deliciously fragrant, chaste in colour, durable when cut, very beautiful for table or specimen glasses, subject to no disease, and most easily managed. In a very neat brick tank at Belmont, Taunton, there are four plants which are admired by all visitors; they have been in flower during the whole season; and even now, when there are no flowers in the garden, these plants are blooming as freely as ever. They should be potted in loam and sand, say in 10-inch pots, then placed in water. The supply here varies from 3 feet above the pot—seldom more than 3 feet. Here they luxuriate. *Nymphaea alba* grows and blooms admirably under the same treatment. Has any one tried to grow *Nymphaea cœrulea* as an outside aquatic during the summer? If it would flourish under the above treatment, what a charming combination and contrast might be made with these plants. *William Payne, Belmont, Taunton.*

Cypripedium Roezlii.—There is now in bloom here (Belmont, the seat of John Marshall, Esq.) a very fine healthy plant of the above, with eight spikes on it. The plant is very healthy, and fully equal to the task of perfecting the flowers which are on and coming forward. There is, however, one peculiarity belonging to this species which I have not observed in any other of the family, and I should be glad to know if the same thing happens in the experience of others. I allude to the flowers falling off at a certain period, when not withered or decayed. This event appears to be regulated by the development of the succession flowers, for when the unopened bloom arrives at a point of about three parts its opening size

then the expanded bloom drops, as if to make way for its successor. I have kept those fallen flowers for a fortnight in very good condition, and cannot account for the occurrence. *W. Payne, Belmont, Taunton.*

Orchids in November.—Although out-of-doors winter is upon us, in the Orchid show-house the season of flowers has begun, and already it is richly furnished, as the following list for November will prove. Readers who desire to cultivate Orchids will see that the greater number of these come from the cool house, and are now also sending forth profusely stems that promise a rich supply through the winter.

Vanda cœrulea	Phalaenopsis cornu-cervi
Cattleya maxima	Stanhopea Wardii

Edward W. Cox, Moat Mount, Mill Hill, Nov. 28.

Strawberry Perpetual.—Amongst a lot of new Strawberries which I planted here one bearing the above name, from its habit and strong constitution, took my fancy. The plant in appearance is a good deal like a Strawberry known in the North as "Black's Seedling," and was rechristened about London as "Black Prince," but Perpetual is distinct from this or any other Strawberry which I have met with. At layering time I gave orders to try a hundred of them, and they were treated in every respect the same as the others, but to my agreeable surprise in October they, without any extra encouragement, came freely into blossom, and appear, with simply greenhouse temperature, to be setting their fruit nicely; and I should not wonder when this Strawberry becomes better known and specially treated that ripe fruit on Christmas Day will be quite possible. Years ago I told a raiser of new fruit that what we wanted now most in Strawberries was a perpetual habit, and here some one has cleverly hit off the very thing wanted. *J. Rust, Eridge Castle.*

Schizostylis coccinea.—Those who have never grown this brilliant Iridaceous plant can have no idea of its value for decorative purposes during the winter, or the great ease with which it may be grown and got into bloom at that season. Just now we have a great many tufts of it in 6-inch pots, and a fine display they make in the greenhouse, where they go on flowering for several months in succession. The best and strongest plants with us are some we raised from seed sown last February in heat, in which they were kept growing gently on till towards the end of May, when they were planted out in a partially shaded position, and kept well watered during the summer. In the early stages of their growth they have much the appearance of young Leeks, but afterwards assume more the habit of Iris, to which in miniature they bear a close resemblance, while the spikes of bloom are almost the exact counterpart of those of the Gladiolus, except that they are smaller and of a bright scarlet colour. Considering its hardy nature, and the length of time it has been introduced, it is surprising it is not better known and more generally cultivated than it appears to be, especially as it flowers naturally at a time of the year when there is little else of a gay character to cheer and enliven. Like its near ally, the Gladiolus, I find the blossoms will continue opening in water almost as well as when left on the plant, and it is therefore a valuable subject for cutting as it lasts a long time in water and quite lights up any vase or perge in which it may be used, ad-

mitting as it does of such ready increase either by seed or division of the root. Those who are not so fortunate as to possess a stock of it will experience no difficulty in working up as many as they may desire by setting about its propagation at once, or by sowing soon after the turn of the year, and treating the young plants in the manner mentioned above. Although perfectly hardy, if disturbed at this season it will be the best way to pot each piece separately in small pots and stand or plunge the same in any cold frame where they are protected from frost and dry cutting winds. In such a favoured position they will be making fresh rhizomes underground and forming young rootlets ready for a more vigorous start in the spring. In the ordinary way, after a sufficient stock is obtained, all that is necessary after they have done blooming is to stand the plants away under the shelter of glass till April or May, and then to shake out and plant as many as are likely to be required, having previously divided them into moderate sized tufts to allow for future growth. The soil for them should be prepared by being made light and rich with leaf-soil and well decomposed manure, and after being dug up and thoroughly incorporated together the plants may be put in at about 9 inches apart. A slight mulching of old Mushroom-bed dung, or anything of that kind, is of great assistance during their summer growth in keeping their roots shaded and uniformly moist, which to water-loving subjects as they are is a matter of some importance, as when they are allowed to become dry they are apt to get red-spider on their flag-like leaves, and when that occurs it causes much disfigurement by turning them rusty. To ward off these pests it is a good plan when giving water to always administer it through the rose of a watering-pot, or to make a practice of syringing them two or three times a week during the prevalence of dry weather. By the end of September or early in October they will have nearly completed their growth and formed most of their flower-spikes, and should then be taken up and potted, after carefully reducing the ball to admit of their being placed in 6-inch pots, in which size they look best and are the most useful for general purposes. After the potting the most suitable place for them is a damp frame where they can be kept close and syringed once or twice a day till they get fresh hold of the soil, after which they can be withdrawn a few at a time as they show bloom and placed in the greenhouse or window recesses in rooms, situations for which they are specially adapted. Where they can have manure-water without being objectionable it will be found of great assistance in helping them to develop their flowers, but if rich soil is afforded them when potting the use of any liquid stimulant is not so much needed, but one thing to be observed is not to allow them to become dry at any time. *J. S.*

Crotons.—It is said that "variety is charming," and that "novelty is the spice of life," and certainly those upon whom devolves the duty of developing the progressively increasing taste for things floral and horticultural act well their part, as also do those who create hybrids at home. Croton Weismanni is a great favourite with me. I knew it before it was introduced to the public, but I have never seen a large show plant of it. Another favourite of mine is Croton majesticus, a rapid-growing plant, and very beautiful. I enclose you three leaves for inspection, and you may fancy how very beautiful a plant must be, nearly 6 feet high, with such foliage as the specimens enclosed. We have lately received Croton Earl Derby, which is strikingly grand in its colouring, and should it prove of good constitution it will make a sensation in the exhibitions. *W. P., Belmont, Taunton.*

Holly Berries.—Last year when the cause of the scarcity of Holly berries was discussed in the *Gardeners' Chronicle*, I gave it as my decided opinion that it was wholly and solely caused by spring frosts, and that, like all other crops of fruit, a severe frost in the time of their being in blossom meant few or no berries; and this season confirms this statement, for the time of the Holly in blossom was truly delightful, and the result is the finest crop of berries I ever remember, and the same may be said of the Arbutus. *J. Rust, Eridge Castle.*

Ricinus Gibsoni.—This is not only one of the most effective of the Castor-oil plants, but is apparently the hardiest of all, for while the green-leaved varieties are destroyed or rendered so shabby by frost and rough weather as to be of no further use, R. Gibsoni is still in good condition and appears as if it would remain so for some time to come. Associated with the beautiful light glaucous foliage of Melianthus major, which has the good quality of being even more hardy, it is very telling during the summer and autumn months from the rich contrast afforded by its dark bronzy leaves and bright coloured stems, which are almost equal in colour to Dell's Crimson Beet, now so much in use for summer bedding. R. Gibsoni is such a good thing as to be quite worth

growing for the decoration of greenhouses and warm conservatories during the winter, where, from its highly ornamental character, it could be made to take the place of such things as Dracenas and other subjects too valuable to be risked in a low temperature. When required for purposes of this kind the seed should be sown in June or July, or cuttings put in about the same time, and the plants grown out in some warm sheltered spot plunged in pots, so as to get them sturdy and strong by the autumn. *S. W.*

The Duke of Buccleuch Grape.—In a note to the *Gardeners' Chronicle* sent on a previous occasion I then said that after further trial of this Grape I would revert to the subject again. I am sorry that my longer experience does not improve my opinion of it; but, on the contrary, makes me more and more sceptical of its merits. Here it grows vigorously, and shows fruit freely, but by no effort of ours can we get it to set, and if any do set they are almost sure to shank, and this in a house in which such sorts as Mrs. Pince's Black Muscat, West's St. Peter's, Foster's Seedling, and Alicante do exceedingly well. If any of your numerous correspondents know of any peculiar treatment that this Grape requires they would confer a favour by making it known, as I should like to be able to grow it. The family here like it very much when a well-developed berry of it can be had. If we may judge by the samples seen from time to time at our fruit shows, I fear there are few persons (if any) who have succeeded in making much of it, but I would faint hope that the Duke is destined to be noble in something more than a name. In the *Gardeners' Chronicle* some five or six years ago Mr. Fowler stood, as it were, sponsor for the Duke, and with a considerable flourish of trumpets helped to introduce his Grace to public notice. It would be interesting to know what Mr. F. thinks of the Duke now. At the risk of being thought presumptuous, I take leave to remark that the placing a few samples of fruit before any number of eminent judges is not sufficient to warrant them in recommending for general planting a thing so permanent as a Vine is expected to be. A few samples might be, and often are, the product of a mere matter of chance. In some situations the failure of a Vine or two is but a small matter, but in the majority of places it is a source of much disappointment, hence the necessity of being guarded in recommending or adopting a new Vine. A four or five years' certificate from the experimental gardens for sure cropping and other good qualities would be better and more to be relied on, and until some such guarantee be given we had better be in no hurry in investing in a new Grape. *J. McC., Alexandria, N.B.*

Lasiandra macrantha floribunda.—I am glad to see the statement at p. 660 that this plant is being successfully grown at Lee Hall. I say now, as I said two years ago, that when well grown this Lasiandra is one of the most conspicuous plants for six months in the year that can be well grown in a mixed stove. Four years ago I introduced one to the roof of a stove, still growing in a 13-inch pot, and from that time it has continued to grow luxuriantly, each season blooming profusely from June to the end of the year. With me Lasiandra has one great advantage over most other stove plants—it is never infested with insects of any description, although grown with other plants that compel one ever to be on the alert to keep them clear from mealy-bug and scale. The treatment it receives with me is this:—After blooming at the end of the year I cut out all the old flowering shoots, tie-in a sufficient quantity of young wood that has not flowered to fill the allotted space, and cut back to three or four eyes all the remaining young shoots; by so doing there is always plenty of strong young wood made for future blooming. The first three months in the year I keep them moderately dry by withholding water from the roots, but being an evergreen I never allow them to get so dry as to shed all their foliage. In April and May they will require a little more water; in June and the two following months I give them an abundant supply with a little extra shading, as I find it is the only thing that they require during the above-named months—different to most stove plants. The Lasiandra will stand as much heat, with plenty of atmospheric moisture, as most stove plants, but it cannot stand the direct rays of the sun so well. As a proof that it will stand a high temperature I may mention that it is growing by the side of Dipladenia splendens that has grown a shoot this season 20 feet long. The blossoms sent are all from the same plant, and I hope they will arrive in good order for your inspection. *William Bishop, Blyburgh Park, East Derham, Nov. 27.* [A fine bunch of flowers. *Eds.*]

The Destruction of Mealy-bug.—One of the worst enemies that many gardeners have to contend against is this insect. When it gets ahead, in a large establishment especially, it is a hard matter to deal with, and the task of eradicating it a difficult one. If

the pest could be stamped out of the country, a great deal of labour necessarily spent on it could be applied to some other purpose. The labour power employed throughout the country might be said, all combined, to more than equal that required to keep in the best order the largest place in the realm. When the mealy-bug gets into ainery there is nothing more annoying to the gardener than to find it in his bunches of Grapes. If the insects have got fairly ahead in the summer it takes a deal of attention to keep them under, and with a lot of other work going on at the time it is almost impossible to do it. But now when the leaves are off is the time to lay the foundation for a complete clearance. The woodwork of the house should be all well scrubbed with soft-soap and hot water, or be painted—the best thing to do if possible. After this the Vines should be well scrubbed with a mixture of tobacco-water, soot, clay, and sulphur [or a strong solution of soft soap]. But in this respect care should be taken in dealing with extreme appliances, such as oils, as cases of vineries being treated with extreme measures have proved a final settlement of the existence of the Vines. If the Vines are infested with bug and now dressed in the usual way, in spring more than likely here and there a few pieces of white down will make its appearance on the Vines and about the house; these pieces of down may each be a young brood of the insect, and every one that is seen should be eagerly destroyed. If this course is followed up the chances are that a house which the previous season was overrun with bug may become quite clear; of course, if dirty plants have been or are put into the house, the cleaning process cannot have fair play. It is a great satisfaction to the gardener when he has no mealy-bug at all to contend with, either in stoves or fruit-houses, more especially if he has had a previous experience with it. Some who are inexperienced are of opinion that wherever certain stove plants are grown, such as Ixoras, Crotons, Francisceas, Stephanotis, &c., there is sure to be found the mealy-bug. This is a mistake, for places exist, although they may be exceptional, where all such as these are cultivated and there is not a mealy-bug to be found. When such a case is found the question arises, What is the cause of the exceptional cleanliness? Is it from the continued watchfulness of the person in charge on the introduction of fresh plants, or is it from some peculiarity of the atmosphere of the place or house? It may be possible that both agencies have something to do with the matter, though no doubt it is mainly through having once got the place clean, then afterwards taking care to keep it so. In some houses, however, it breeds much faster than in others, more especially in iron houses, as they get so hot in summer. *Experience.*

Peaches and Nectarines.—The season has been bad—the worst I ever knew; still, with 121 trees out-of-doors and eleven under glass, I had as much fruit as I wanted, which lasted from August 26, with Early Louise, till October 8, with Nectarine Peach and Princess of Wales. Let me here speak of Parham's glass copings. On October 8 I was at my friend's, W. Connop, Esq., of Fifield Neville, and saw a most triumphant and magnificent sight of Peaches under the glass copings. They were chiefly the Princess of Wales, ripe, and large as cricket-balls. The gardener is not a professed gardener, but a humble hard worker, and modest. On October 8 he had taken off two dozen and a-half of Peaches before I viewed the trees. He pointed to a Nectarine tree under the glass copings, and said, "I disruted 150 Nectarines off that tree, and have landed off it 150 Nectarines. I should introduce here Parham's glass copings were it not for the high winds and the low walls—none above 7 feet high." It is a great misfortune to lose a crop of these fruits where the trees are in high condition, because the wood for another year is apt to grow too coarse, and also, unless the autumn is dry, to be unripe. Ripeness of wood is one of the grand keys of success. I have all the old sorts, and a great many of the new sorts. I recommend these:—Peaches: Early Louise, Dr. Hogg, Early Alfred, Royal Ascot (Standish), the finest coloured of all Peaches; Early York, Early Victoria, Grosse Mignonne, Royal George, Noblesse, Bellegarde, Barrington, Nectarine Peach, and Princess of Wales. These are, in my opinion, the pick of the Peaches. I have others, English and Americans, but they are not equal to those named. As to Nectarines the best are Downton, Elruge, Violette Hâtive, Lord Napier, Rivers' Orange, Rivers' Pine-apple, Rivers' White, and Emmerton's White Nectarine. If the reader gets the above Peaches and Nectarines he will be right. If it were not for mildew under glass, or in hot smoky gardens, I have no hesitation in saying the Royal George is the best Peach in England to have. It does well and is the best in my cold exposed garden on walls E., W., and S. It is short-jointed, and the best setter under difficult circumstances. I am going to try a dozen cut-backs of the Royal George on my north walls, in front of which is a sunken vale of 20 miles to Mere in Wiltshire and 12 miles to Shaftesbury; I have no

doubt the Royal George will acquit itself. Much has been said about pruning, I pinch all summer, and am now cutting out superfluous and useless wood. I use M. Auber's *secateur*, to whom great thanks for one of the best garden instruments: he deserves the thanks of the pruning world. I do not advise persons who do not know the difference between a leaf-bud and fruit-bud to prune now. As regards pruning, I never at any time of the year leave on wood which appears to be useless. The Snow Peach, white blossom, is here, and appears to be worthless; Tippicanoe is untried; Stump-the-World is no better than our own. The golden-fleshed are not so good flavoured as the white-fleshed. The best golden-fleshed Peach here is Mr. Turner's gift, the Golden Frogmore; the golden-fleshed are valuable to vary dessert—use sugar with them. *W. F. Radcliffe.*

The Deciduous Cypress.—I have read with much interest the remarks of "P. P. C.," H. W. Ward, and W. Gurney, respecting the deciduous Cypress. I beg to inform those and others interested in such trees, that there is one here, in the beautiful grounds of E. A. Drummond, Esq., which measures 85 feet in height, and 11 feet 4 inches in circumference at 4 feet from the ground. The trunk is straight and clean for about 25 feet, at that point the tree assumes two leaders; though it is deprived of a few branches by the rough winds it is exposed to from time to time, it is nevertheless a handsome tree, and the finest I have ever seen of its class. The tree grows in a light gravelly but wet soil, and about 8 or 9 yards from it is a large sheet of ornamental water. The heavy winds of late have destroyed the beauty of its foliage, or otherwise it would now have been grand. *G. Mussell, The Gardens, Caillard, Hants.*

Veitch's Autumn Broccoli.—Veitch's Giant Cauliflower has almost a world-wide reputation, and I do not suppose there is a garden in the kingdom in which it is not grown, so indispensable is it looked on to carry on a supply when other kinds fail, through the heat and drought of summer. Following right on the heels of this comes their new autumn Broccoli, which is in every respect equal to the far-famed Cauliflower, indeed so much alike are they that the one might pass for the other, and all the difference there appears to be is in the time they are ready for use. In this Broccoli we have what has long been wanted, and there will be no difficulty now in compassing the whole year through, as it will exactly fill up the void, and last on till Snow's, Backhouse's, and others come in. *J. Sheppard.*

Shade Loving Plants.—I beg to thank "Constant Reader" for his kindness in making out a list of shade-loving plants. If it does not take up too much of your space, I should like a little more information, and I think the subject would be interesting to many of your readers. The most ardent lover of flowers have often only limited garden room, and wish to make the most of every corner, whether shaded or not. Referring to "Constant Reader's" list of plants, I should like to know something more about the Allium Moly; common Ramson is only too common with us, and if this Allium has the same smell and the same spreading habit, I think we will do without it, unless it is very handsome indeed. [Pretty yellow flower, not so objectionable as the other.] I never saw the Alströméria to know it, and should like some further description, nor do I know the Dondia, but I find it is an umbellate, and I don't much care for them; *Egopodium* I shall certainly not try. Some of the names of bulbs I am very glad to hear of as shade-loving—*Galanthus plicatus*, *Crocus sativus*, and the *Scillas*—but will the *Ornithogalum* open without sunshine? I have just looked out *Gagea* in Bentham, and I think from the description it must be the flower I once saw blooming all over a little garden in front of a house in the City Road, London. It was some years ago, but I cannot forget how refreshing its cool yellow petals looked on a hot day, growing as they did out of ground as hard as a road, and shaded by tall trees. I shall certainly get some of them for my border when I can. The *Meconopsis*, and *Tradescantia*, *Geranium Andresii* too, I am glad to be reminded of, they are worth the space they will cover; but hardly so the *Galeobdolon*, *Asarum*, or *Anchusa sempervirens*. These things may do in the corners of shrubberies, but they have not sufficient distinct beauty for the border. *Gentiana acaulis* I know will not do in the shade, and I hardly think *Fritillaria Imperialis* will, but *F. Meleagris* grows well here among the grass on a part of the lawn partially shaded. We grow *Cyclamen hederifolium* in the same way; this beautiful little flower really does well in the shade. *C. europæum* we have, but it does not flower, neither does the *Vinca* appear to flower well without sunshine; and *Saxifraga umbrosa*, though it likes to be shaded by a rock or wall, does not do well under trees. I think the same may be said of the *Caltha*, has "Constant Reader" tried it under trees? We have *Aconite*, *Corydalis bulbosa*, *Leucogonum*, *Omphalodes*, *Pulmonaria*, and *Funkia*, and the lovely *Anemone*

apennina; but the best ornament of our most shaded parts is the Martagon Lily in its season. Are there not other Lilies which love the shade? We are trying *Lilium giganteum*. I am anxious also for some information about *Aquilegia*. I have some nice seedlings of *A. Skiinneri* and *A. chrysantha* coming on, and I should like to know how they should be treated. Are there any good hardy *Oxalids*? *Trowel*.

Hardy Herbaceous Plants for a Border Shaded by Trees.—The plants in the list which I give below will thrive in such positions as "Trowel" speaks of in his letter at p. 566. Before proceeding to give their names I would just make the important remark, that if the border is so near to the trees, or the trees so large as to have entirely filled the border with their roots, these should be severed by means of trenching the border to the depth of 1½ to 2 feet deep. First of all I will enumerate those plants whose flowers are blue or colours approaching blue:—*Omphalodes verna*, intense blue, Forget-me-Not like flowers; *Lithospermum purpureo-ceruleum*, the beauty of this plant is enhanced by being grown in shady positions; *Iris germanica* *I. pumila*, *Gentiana gelida*, *G. asclepiadea*—for these two latter add a little peat to the soil; *Hepatica triloba*, the single and double forms; *Campanula macrantha*, *Lupinus polyphyllus*, *Ajuga genevensis*, *Anemone apennina*, *Aquilegia vulgaris*, *Polemoniumeruleum*, *Scilla bifolia*, *S. sibirica*, *S. campanulata*, *Veronica gentianoides*, *Vinca major*, *V. minor*, *Viola cucullata*, *V. striata*, *V. odorata*, and its varieties. *Symphytum caucasicum*: this is the best plant I know of for growing under dense shade of trees; the flowers, too, are very beautiful, but the plant requires plenty of ground to ramble about in: it is not suitable for association with smaller kinds, as it would soon overrun them. **Plants with White Flowers.**—*Erythronium dens-canis album*, a most lovely plant for such positions; *Anemone apennina alba*, *A. nemorosa* and its double form, *Helleborus niger*, *H. maximus*, *H. orientalis*. This has creamy white flowers, the foliage is large and distinct. *Hepatica*, single white; *Paeonia chinensis plena*, *Iris florentina*, *Vaccinium vitis-idaea* (peaty earth); *Saxifraga affinis* forms a carpet of lovely green, the flowers are not conspicuous; *Scilla bifolia alba*, *S. campanulata alba*, *Spiraea japonica*, *S. filipendula plena*, *Symphytum ibericum*, a plant with cream-coloured drooping flowers—from 9 to 12 inches high—grows very freely; *Thalictrum aquilegifolium*, *Trillium grandiflorum*, a most lovely plant, it thrives best when planted in damp peaty earth, and enjoys the shade of trees. **Plants with Yellow Flowers.**—*Hemerocallis flava*, *H. lutea*, *Anemone ranunculoides*, *Dondia epipactis*, *Doronicum Chesii*, *D. caucasicum*, *Trollius asiaticus*, *T. europaeus*, *Genista sagittalis*, *Erythronium giganteum*, *Primula sikkimensis*. The last two plants would require a damp situation, and the addition of peat earth or leaf-mould. *Polygala chamæbuxus*, a well-known plant with evergreen Box-like foliage and lemon-coloured fragrant flowers; *Solidago Virgaurea*, *Iris flavescens*. **Plants with Rose or Pink Flowers.**—*Erythronium dens-canis*, *Hedysarum obscurum*, *Helleborus atrorubens*, *H. olympicus*, *H. colchicus*—the flowers of this latter species are coppery plum-coloured; *Hepatica*, single and double-red; *Lathyrus grandiflorus*, *L. latifolius*. *Cypripedium spectabile* will thrive under the shade of trees if the soil is not too dry, by adding a good quantity of peat or leaf-mould. *Peonies* in variety, *Cardamine latifolia*, *Colchicum autumnale*, in variety; *C. speciosum*, a beautiful kind; *Cyclamen hederifolium*, *C. neapolitanum*, *C. europæum*, *Polygala Brunonis*, a very useful plant for autumnal display; *Primula cortusoides aemœna*, *P. pulcherrima*, *P. purpurea*. These have purple or slaty-purple-coloured flowers—they are extremely fine flowering, as they do so early in spring. *Silene caucasica plena*, a showy plant, but requires plenty of room; *Spiraea venusta*, *S. palmata*, in damp soil; *Tusilago fragrans*. The following are worthy of cultivation for the beauty and grace of their foliage:—*Bambusa metake*, *Thamnocalamus Falconeri* (*Arundinaria falcata*), *B. gracilis*, *Osmunda regalis*, and other Ferns, especially the *Struthiopteris*; *Arundo conspicua* and *Glycerium argenteum* will grow if not too densely shaded; *Libertia ixoides*, *Polygonum cuspidatum*, *Palmetaria sibirica*. *R. P., Holgate, York.*

The Hardiness of Desfontainea spinosa.—At p. 597, col. c, are two letters touching upon the hardiness of *Desfontainea spinosa*. May I ask what is the possible use (in speaking of the hardiness of a plant) of a man signing himself "Cambrian" and another "Broughty Ferry?" "Cambrian" may live at the south-west corner of Wales, on the sea-coast, and "Broughty Ferry" may be known to people living there or the inhabitants of Dundee, but why cannot the correspondents say where their localities are, and whether subject to sea influences? All I know is that this beautiful shrub will not stand here, 12 miles south of London, as I know to my cost. Pray ask your correspondents to be more explicit.

A. R. [We should be very glad if they would do so. EDs.]

Root-pruning.—I advocate attention to the roots, especially of fruit trees, and hope now that we have had the admirable papers by "Observer" and Mr. Boulger, that the root theory will have the attention which in my opinion it deserves. From my experience I would say, give the roots the pruning and the food they require, and you will have little need of the finger and thumb process, or of the use of the knife either. I cannot dispute the success which may result from the summer pinching if the soil is all that can be desired, but with a bad soil that is liable to get sodden in very wet weather, or very hard in very dry weather, I say "lift," either annually or biennially, giving nutriment at each operation if required, and you may expect results to your satisfaction. I am a little doubtful of the ultimate health of trees that are either much pruned or severely pinched. In the summer, apart from the excess of duties demanding attention just at this time—but perhaps I ought not to refer to busy time when the operation needs attention, the lifting and root-pruning incur very much time, as in fruit thinning, at least I found it so when I practised it; I hope I may be able to practise it again ere long. Had I not been disturbed in my then garden my trees would now have been some of the finest in the world, simply from lifting and root-pruning. I have never seen such leaves and flowers anywhere, and the fruit, some of which were sent to Dr. Hogg, were such that in a letter from him he said that he had never seen "such, except on the Continent, where it was grown for show and not for use." Not only were the fruits large, but so beautifully coloured too; Apples about 1½ lb. each, and Pears over a pound, and not from a wall but from pyramids or bushes. *George Lee, F.R.H.S., Clevedon.*

Christmas Rose.—Of all hardy plants this is certainly one of the most serviceable, affording as it does an abundant supply of flowers for cutting at a time when they are generally much in request and not over plentiful. Not only is it of great use for the above purpose, but it is equally valuable for pots to use in the greenhouse or window recesses in rooms, for the latter of which positions it forms a charming ornament of great powers of endurance, owing to the thick texture of its leaves and the immense substance of its fine waxy-looking blooms; the stems, too, that support these, being large and porous, take up water freely, in which, when placed with flowers even in the bud state, they absorb sufficient to induce them to expand almost as well as if left on the plant. Although generally supposed to be slow to increase, I have not found it to be the case with *H. niger maximus*, which is by far the finest and best of all the species, as, after obtaining three clumps last autumn, I was enabled, by shaking them clear of all soil and carefully separating each crown, to increase them to twenty-five, only one of which failed to grow. The situation I chose to plant them is a narrow border, at the sunny end of a greenhouse; that appears to suit them admirably, as they have all made fine crowns and are producing a profusion of blooms. In a position of this kind they get shelter and can easily be protected by leaning some old lights over them on the approach of bad weather. So favoured, the flowers come with much greater purity of colour, and free from that disfigurement to the edges of the petals in the way they are generally affected when exposed to wind and wet, and allowed to take their chance. To grow them well and strong they require a light, deep, rich soil, and if of a peaty nature all the better, as they delight in decomposed vegetable matter, and if peat is not easily to be had, plenty of leaf-mould should be worked in instead with a little road scrapings or sharp sand to keep the whole open and porous. In ground prepared in this way, and with occasional waterings during the summer, they will luxuriate and make plenty of foliage, on the free and full development of which much of the success in flowering these most useful plants depends. For pot work it is best to take them up about the middle of October, and to put them under cover in cold frames, where they can be kept with plenty of air till they get well into bloom. It should be borne in mind that, hardy as they are, they are very susceptible of injury after being housed some time, as the leaves do not acquire that degree of firmness and leathery texture so characteristic of them when fully exposed to the weather. This being the case, any that are used as pot-plants should not be turned out in the open as soon as their beauty is over, but be kept in some cool light place till all danger of severe frosts is over. *S. H.*

Potato Disease: How to Guard against It.—I saw in your issue for October 27 a paragraph on the management of Potatoes, in which the writer suggested two methods of saving the crop from disease, viz. :—1, to pull up the stalks, leaving the tubers in the ground; and 2, to cut them off close to the ground. I have tried both plans, and in

each case think the Potatoes were injured. In the first place they stopped growing, in the second they lost flavour, and were close and soapy. This year I adopted another plan, namely: Having the rows 24 inches apart, I set the Potatoes 6 inches apart, and as they advanced in growth I followed the old plan of earthing-up, but with this difference—I did not draw the soil close to the stalk, leaving room for another earthing at such time as I thought proper. In this I should be governed by the state of the weather. Should it be fine, I let them remain in an upright position until the first appearance of the flower-buds, when I turn the rows over with the handle of the spade. On reaching the end of the row, I at once commence with a narrow spade to place sufficient earth to prevent the stalk from rising upright. In a few days the tops will be found drawn up by the light, as shown in the figure. I am glad to say that I found this a perfect success. The experiment was tried with Early Rose and the Royal Ashleaf Kidney. To prove it, I left some rows not turned down. In either case the crop was good, some of the Potatoes weighing 1 lb. each. The tops were alike spotted with the disease or fungi, but not so with the Potato itself. Those done as I have shown were found good and free from disease when taken up, whilst those earthed-up the second time were for the most part had. *R. Inch, Gr., Hache Court, Taunton.*

Large Willows.—Beside the burn which flows through the holm just outside my garden there were some large Willows, grand old trees which had stood out, and suffered from, many a severe storm. At last they showed signs of such decay that it was resolved to cut them down. This resolution was the more readily acquiesced in as their removal certainly opened up a good view along the course of the river, and during my absence abroad last winter three of the trees were cut down to the ground, and one was cut to within 8 feet of the ground. Of this old trunk I send you a rough sketch. The dimensions are, from c to d, 7 feet 11 inches; and the girth, from a to b, is 12 feet 1 inch. It strikes me that this is rather an uncommon girth for a Willow: from the ground to place of measurement is as near 4 feet as it can be. You will observe that the tree is making vigorous efforts to throw out young shoots. On the other side of the tree there was a third branch springing a little lower from the trunk than the two shown at d, and just below the line of b on the other side is another bole or excrescence like the one from which the young shoots are springing so lustily. In a few days more I shall be leaving this place, and may never have the opportunity of seeing the old tree again, so I venture to send you its measurement as an addition to the records of girths of trees which you publish from time to time. I have also measured the flat surface of one of the other Willows cut level to the ground, and send you an outline of its shape with the dimensions:—A to b, 4 feet 1 inch; c to d, 3 feet 3 inches; e to f, 3 feet 1 inch. Following the shape closely, the measurement is 12 feet. Being flat to the ground this is, of course, no test of what the measurement was at 4 feet from the ground, and from my recollection of the tree I think I may safely say it was quite 2 feet less in circumference than the one of which I have sent you a sketch. *J. A. C., Annan.*

The Rival Ivies.—It would almost seem that the gentleman who writes from Ireland (Mr. Smith) had felt a kind of personality in my remarks on the comparative value of the two Ivies. Whether Mr. Smith's desire was to add some remarks of his own, or to call mine in question, does not plainly appear. There is no doubt the term "Irish Ivy" is a trade one. Whether the latter Ivy is a species or a sport I cannot say; if the latter, it is very marked and permanent; and as to not knowing where it begins or ends, it would not do for a tradesman to offer intermediate for it. Mr. Smith seems to have our native plant in view when speaking of variability, which I admit, but I never knew the Irish Ivy to vary except into variegation, or the arborescent form which all Ivies will assume conditionally. It is granted the plant in question must be shorn like a sheep, and as the Ivy appears to look the best when re-leaving after the operation, so the other appears the handsomer when newly shorn. But the labour! It is no small matter to shear the side of a three-storey mansion. I have seen a man up a break-neck-looking ladder at the operation for days together; and as regards the seeming exaggeration about the comparative quantity of leaves on the two plants, I will again repeat that in draughts, close passages, or very shady places, where the common Ivy would be a sheet of emerald, the Irish Ivy would be nothing more than a network of bearded stems. In conclusion, my remarks on the two Ivies have been answered, but not contradicted; and but that I have been misrepresented I should not have written this. Mr. Smith may "think exactly" (as he admits at the commencement), but he does not quote exactly at the

end, where mention is made about the plant being difficult to propagate. There is not a word about this in my communication. I thank Mr. Smith for the information about the bed of 100,000 seedling Ivies. I must confess I was in ignorance that Ivies to such an extent were propagated in that way, and I must say this is something new under the sun. *Thomas Williams, Ormskirk.*

The Wilson and other Cress Rafts.—Shortly after the notice of the above in the *Gardeners' Chronicle*, Charles Beard, Esq., of Bury St. Edmunds, the talented inventor of Beard's metallic hothouses, invited me to see a Watercress raft in his garden reservoir. It was formed of a sort of floating basket, and had been employed for many years for the growth of Watercresses for household use. The raft had the free run of the reservoir, which is not very large, and answered admirably, seldom failing to yield a good supply. It was sometimes found at one side of the fountain, sometimes the other, according to the set of the wind. This is an admirable use for floating rafts such as Mr. Wilson describes. It would add an additional charm, if not a new sweetness, to the Watercresses to be grown thus in one's own garden. Those that have larger lakes or ponds could easily moor these rafts to the shore, so as to haul them in when wanted; or, where the water was large enough for the use of a boat, a raft hunt for Watercress might prove a useful constitutional for breakfast or tea. Mr. Beard has another simple contrivance for keeping the water in his fountains sweet and pure. The pipe rises to a considerable height in the centre, and, unless the fountain is wanted to play for effect, the waste is carried from thence to the bottom of the fountain; the water is by this simple contrivance renewed from the bottom upwards, instead of from the top downwards, and the result is that the water is always clean and sweet. It is not probable that this method of renewing the water has had much to do with the luxuriant growth of the Watercress, but it is a fact of great practical moment if water can by this simple and unusual method of replenishing be kept pure and sweet for years. The overflow of waste water is placed an inch or two below the upper edge of the reservoir. It is just possible that as the sea beyond a certain depth of the surface is always calm, however wildly the waves roll or breakers dash on the surface, so fountains furnished with water from the top in the usual way are only partially renewed; hence the stagnant water underneath runs into putridity and becomes offensive, while by renewing and also gently agitating the whole mass of water from the bottom upwards the whole bulk is changed, and this renewal preserves it sweet. Be the cause as it may, Mr. Beard assures me the facts are as stated, and the water was specially sweet at the time of my visit. *D. T. F.*

Desfontainea spinosa.—I am glad to find "Cumbrian" (see p. 597) speaking so well of this much neglected but beautiful shrub. It ought to be planted in all collections of choice flowering shrubs. We had it in flower at Woodstock in July, and it has now (November 20) quantities of flowers fully expanded, a few of which I enclose. I find cuttings put in about the middle of February take root freely. We simply put in the cuttings, say two dozen in a 6-inch pot, and then plunge them in coal-ashes in a cold frame, and there leave them until the autumn, when they are potted off into 4-inch pots and replunged in ashes. As this shrub is so beautiful and perfectly hardy why not have hedges and banks of it instead of the everlasting Privet, which requires such constant and continual clipping to keep it in order? *G. Dodd, Woodstock Park, Kilkenny.*

Protection of the Pampas Grass.—The writer at p. 531 suggests covering this plant with coal ashes. What are we to do with the beautiful silver spikes now in bloom? Must they be destroyed? As to the noble plants seen in Madeira, which stand so prominently on many a lawn, some being 5 feet in height and 10 feet in circumference, I would ask are we to have mounds of coal ashes this height on the lawn? I have found the green sward a sufficient protection from the frost. *R. Inch, Gr., Hucho Court, near Tunton.*

"PUNCH" TO DR. DARWIN.

OUR world's stage footlights flare and fume,
While the clear light that shall illumine
The Future's farthest ages
In quiet sanctums fend desecry,
Still trimmed and tended patiently
By unobtrusive sages.

And when that light begins to show
Its keen but unfamiliar glow
To poor be-muddled mortals,
The dullards blink, the quidnuncs croak,
The zealots fain would Heaven invoke
To bathe those perilous portals.

In vain: that clear and conquering light
Wins as it widens, calms affright,
Dull souls from dread delivers;
Till they who came to curse make shift
To give a welcome to the gift
And honour to the givers.

So comes my Darwin's turn of praise
And the green honours of their Bays
The men who banned you offer;
The smile, of such occasion born,
Might well have had a touch of scorn,
Could Wisdom be a scoffer.

But only shallow smartness mocks
The antics of the orthodox,
The dogmatist's wild capers;
Smile, but ne'er lift the heel to spurn:
Trust Truth's asbestos to outburn
Delusion's glimmering tapers.

Science should be the last to claim
Infallibility's false fame,
Which only Folly urges.
The truth to seek with patient quest
Is hers, content to leave the rest
To blatant Boanerges.

So have you done; the road you tread,
As free from rashness as from dread,
You follow without swerving.
Fame meets you fairly on the way,
And where 's the duffer who to-day
Dare question your deserving?

Punch cracks his jokes at you sans ruth;
His honest fun was not with Truth,
But rather serves to test her;
And, serious now, he bows respect,
Sure that the Sage will not reject
The tribute of the jester.

Punch.

CHRYSANTHEMUMS AS DECORATIVE PLANTS.—At the Ealing nurseries of Messrs. Charles Lee & Son, Mr. George Cannon, the able manager, has afforded another illustration of the admirable way in which that most useful of autumn flowers—the Chrysanthemum—can be utilised as a decorative agent. There is in the nursery a house 50 feet in length by 20 feet in width, which is used during winter and spring for housing orchard-house trees in pots; and it occurred to Mr. Cannon that a house of Chrysanthemums would be an attractive object to the flower-loving public of this rapidly-increasing district. The house is now filled with admirably-grown and finely-bloomed plants, carrying flowers of excellent quality, and the collection serves to show not merely what a "flush of hues" can be had in the autumn months when scarcely a gleam of colour is visible in many outdoor gardens; but also the best varieties that can be grown for the purpose of conservatory decoration.

The house being spacious requires a good number of plants to fill it, and there are three or four of a sort of the following varieties:—Abbé Passaglia, Barbara, Beethoven, Beverley, a very fine white; Dr. Sharpe, Duke of Edinburgh, very pretty indeed for conservatory decoration, but not adapted for show purposes; Empress of India, Golden Empress of India, a splendid exhibition variety; Grand Lodge Rival, a kind of dark-bronzy gold, distinct and fine; Felicity, with large half-reflexed flowers, white, with lemon centre, appearing as if intermediate between the large-flowered and Japanese varieties; George Glenny, Golden Beverley, Golden Queen, Guernsey Nugget, a rather late variety that keeps its foliage remarkably well; John Salter, Julia Lagravère, Lady Talfourd, Mr. Dixon, Golden Mrs. George Rundle, Mrs. George Rundle, with flowers of a remarkable size; Prince of Wales, Queen of England, Virgin Queen, probably the purest white Chrysanthemum in cultivation; White Globe and White Venus, with that fine white Anemone-flowered variety, Lady Margaret. Of Japanese varieties there were Diamond, very fine; Crykang, Fair Maid of Guernsey, Glitter, in the way of Diamond, deeper in colour, but of delicate habit; Gloire de Toulouse, James Salter, Meg Merrilees, The Cossack, and Ville d'Hyères, dark reddish maroon pointed with golden-yellow.

The plants averaged from 3 to 5 feet in height, with a main stem, and three or four leading stems branching out 18 inches or so above the pot. There are about 300 plants, mostly in 12-inch pots, and being tastefully arranged they make a most effective display. The method of culture adopted by Mr. Cannon may afford a valuable hint or two to those interested in the cultivation of the Chrysanthemum. The cut-

tings were struck in an ordinary dung frame in February, and grown on in 60-pots, and early in May hardened off when the plants were a foot or so high, and of a sturdy character; then they are allowed to break out to three or four leading shoots. In June they were potted into their flowering pots, stood out in the open air, and never allowed to suffer in the least for want of water, and two or three times a day were thoroughly drenched overhead from a hose. Some manure-water judiciously administered at blooming time gives size and brilliancy to the blossoms, and he who was never before moved to admire Chrysanthemums could scarcely look upon the contents of this house, and then pass out, without being fired with admiration, even if he were not incited to attempt something of the floral treat so lavishly set forth. *R. D.*

Reports of Societies.

The Birmingham and Midland Counties Chrysanthemum Fruit and Flower Society.—The seventeenth annual exhibition of Chrysanthemums and other plants, flowers, fruit, &c., was held in the Town Hall, November 21 and 22.—The Chrysanthemum plants as a rule were inferior to those displayed in previous years, really good plants being the exception, the backward season having shown its influence on the exhibition. There are plenty of fine plants about Birmingham, and if the exhibition had been a fortnight later, Chrysanthemums would have been then in great force. Examples of a hideous system of training were there, which merited and received general condemnation. These were large but apparently tolerably well-grown plants, but tied down closely to a large flat circular form, and all traces of the natural growth of the plant were lost, and in most instances it was palpably clear that the tying down had been done the day before, and what few blooms there were had a very lopsided appearance. Mr. Newell, gr. to Mr. L. Hayman, obtained the 1st prize for nine large-flowering kinds, and Mr. Padbury, gr. to Mr. R. P. Yates, the 2d prize. For six plants, Mr. Denning, gr. to Mr. J. Fenton, was 1st, and Mr. Shepherd, gr. to Mr. W. Warden, 2d. For nine Pompons: 1st, Mr. Padbury; and for six Pompons: 1st, Mr. Doughty, gr. to Mr. H. Hayman. One of the very best plants in the exhibition was a plant of Mrs. Dixon, a fine yellow, exhibited by Mr. Denning.

The cut blooms were not numerous, but some of them were very fine, and in the open class for eighteen Mr. Silver, gr. to Mr. S. A. Everett, had a grand bloom of Queen of England, not so white as usual; Prince Alfred, very fine; Empress of India, Fingal, a fine purple; Guernsey Nugget, Cherub, Lady Talfourd, Mrs. Haliburton, Lady Slade, Gloria Mundi, Mrs. George Rundle, Beauty of Stoke, Mr. Gladstone, Jardin des Plantes, Isabella Bott, Lord Derby, Lady Harding, and Baron Beust, fine. These blooms were a very fine lot indeed, and took the 1st prize, the 2d prize falling to the gardener to Mr. R. Bradley. For twelve blooms Mr. Silver was also 1st with very fine blooms of kinds shown in his eighteen, Mr. Dyer, gr. to Mr. T. W. Webley, being 2d.

In the class for eighteen blooms for growers within 3 miles of Birmingham Mr. Dyer was 1st, in whose stand were fine blooms of John Salter, Jardin des Plantes, Prince Alfred, and Mrs. Dixon; 2d, Mr. Denning, gr. to Mr. J. Fenton.

There was a very nice display of plants, and in the collection of nine Mr. Walter Jones, gr. to Mr. Councillor Matthews, took the 1st prize, and this collection included a grand Chorozeema Hendersoni and a fine Cocos Weddelliana in flower. Mr. Jones always exhibits successfully, and turns out his plants in a masterly manner. Mr. H. Lea was placed 2d with a capital lot, and Mr. Crisp, gr. to Mr. B. Scarf, took the 3d prize with a very creditable lot.

In the class for stove and greenhouse plants Mr. Dyer was placed 1st, and in his lot were well-grown and beautifully coloured examples of Croton variegatus and C. angustifolius.

For special prizes, offered by a member of the committee for nine stove and greenhouse plants in pots not exceeding 8 inches in diameter, there was a close competition, and a lot of plants which cheered the heart of those who prefer such to the elephantine specimens often seen. The 1st prize fell to Mr. Dyer, who had Abutilon marmoratum variegatum in fine character, and beautiful plants of Maranta Veitchii and Dracæna Macleayi. Mr. Stacey, the treasurer to the society, had a nice lot which ran a close 2d, and included a fine variegated Curculigo and a good Cocos Weddelliana.

The Chinese Primulas were, however, the great feature of the exhibition. Birmingham stands out prominently in Primula culture, and at its head stands Mr. Tomkins of Sparkbrook, one of the oldest nurserymen of the town, and his strain of Primula of the Princess Louise and Marquis of Lorne type,

two well-known varieties of his own raising, have a great local celebrity. These are the progenitors of other varieties which, with the parent kinds, form a distinct strain of Primulas which should be known as Tomkins' Birmingham Prize Strain, and not as anybody else's. They are wonderful in form, size, substance, and colouring, and one variety, named Scarlet King, is of a wonderfully bright colour. Mr. Tomkins took several 1st prizes, his six Fern-leaved varieties being marvels of Primula culture, and he took a 1st prize for six fine double varieties of his own raising.

In the gentlemen's gardeners' classes for Primulas there was a hotly contested competition, not an indifferent lot being staged. In the class for twelve, Mr. Caldecott, gr. to Mr. William Matthews, was 1st, Mr. Denning 2d, and Mr. Doughty 3d, an extra prize being awarded to Mr. Shepherd for a fine lot; so that some idea may be formed of the excellence of the collections obtaining the higher prizes.

Mr. Thompson, seedsman, Birmingham, offered extra prizes for twelve Primulas, open to gentlemen's gardeners only, and the competition was very close indeed, so close that equal 1st prizes were finally awarded to Messrs. Dyer and Caldecott. Mr. Crook, gr. to Mr. W. Millward, took the 1st prize for six good Cyclamens, and Mr. Stacey 1st prize for Solanums.

Bouquets were a decided feature of the exhibition, Messrs. H. Pope & Son, Birmingham, obtaining the 1st prize with a handsome bride's bouquet; and Mr. Walter Jones a 1st prize for a handsome ball-room bouquet. Messrs. Felton & Sons, Birmingham, sent, not for competition, a very handsome bridal bouquet, which was much admired, and was made up by Master Felton, a young gentleman who has just attained his fifteenth year; so our older bouquetists must look out for their laurels.

THE FRUIT made a good display, especially in Grapes and Apples. There were five exhibitors of three bunches of black Grapes: 1st prize to Mr. W. H. Clark, gr. to Lady Edwards; 2d to Mr. Dyer; 3d to Mr. Chadwick, gr. to Mrs. Nilson; and an extra to Mr. A. Sayers, gr. to W. H. Wynn, Esq., all really good. Three bunches of white Muscat Grapes from Mr. Sayers were grand, highly finished, of a rich golden-amber colour, and good in berry and bunch, and won in a canter the 1st prize. In the class for single bunch of black Grapes, Mr. Dyer was 1st with a capital bunch, Mr. Chadwick 2d, and an extra to Mr. Clark. In white Grapes, Mr. Bannister, gr. to Mr. W. H. St. Vincent Ames, was 1st with Bowwood Muscat; 2d, Mr. Cushion, gr. to Mr. W. E. Wiley. For a collection of fruit, eight varieties, Mr. Chadwick was 1st, and Mr. Ashmore, gr. to Captain Cox, 2d.

In the class for six dishes of Pears there was not much competition, but Mr. W. Gardiner, gr. to Mr. E. P. Shirley, won the 1st prize very easily with a fine lot, consisting of Beurré Diel, extra fine; Easter Beurré, extra fine; Beurré Rance, Glou Morceau, Doyenné du Conice, and Passe Colmar.

For twelve varieties of Apples, as well as for six varieties, Mr. Gardiner was 1st, with grand fruit, large and richly coloured. His varieties consisted of Dumelow's Seedling, New Hawthornden, Wyken Pippin, Ribston Pippin, extra fine; superb Blenheim's King of the Pippins, Cox's Pomona, Yorkshire Greening, Flanders Pippin, very fine indeed; Hanwell Souring, extra fine; Lord Derby, a grand dish of Belle de Bois, and Hawthornden, very large and wonderfully bright in colour, which Mr. Gardiner says were grown on a tree not perceptibly larger than it was fifteen years ago. Mr. Bannister was 2d with a fine lot, including very fine Kentish Pippins, bearing a close resemblance to Blenheim Pippin, but not so well coloured; Blenheim, grand in colour; and King of the Pippins, very bright in colour, almost red. Mr. Chadwick was 2d for six dishes, which included Glory of the West, a very fine kitchen Apple, Pike's Pearmain, a bright-coloured handsome dessert fruit; and the Shilling Apple, a very bright striped showy variety. Mr. T. C. Boston, of Acock's Green, formerly manager of Messrs. Carter & Co.'s nursery at Forest Hill, contributed a collection of dried specimens of eighty-six varieties of Ericas, and about 150 varieties of Ferns and Lycopods, all life-size, and admirably mounted and of especial interest, and to which a special prize was awarded. Mrs. E. H. Hodgkins, 35, Hyde Grove, Manchester, contributed a most beautiful display of examples of botanical anatomy, which proved a marked feature of the exhibition and received great praise and a special award. This lady is a medallist of the Royal Horticultural Society, and has devoted much attention to skeletonising leaves, and they are of rare beauty, especially a fine group of Ficus Porteana foliage, which required twelve months in the preparation and completion; seed-pods of Poppy, or rather the mere skeleton of the seed-pods; Fern fronds most beautifully bleached by a process of Mrs. Hodgkins'; and artistically arranged groups, showing the beauty of botanical anatomy, were plentiful.

Mr. R. H. Vertegans, of the Chad Valley Nur-

series, exhibited a plant of Colonel Trevor Clarke's new Begonia Moonlight, a plant of great beauty; a large group of Poinsettias, fine in growth and foliage and in the richness and size of the bracts; a basket of Azalea Blanchard, pure white and very early, the best and earliest forcing kind we have; and a group of Biota semperverea, as golden as a field of richly coloured Wheat.

A satisfactory staging of a multitude of things in a building such as the Town Hall is difficult, therefore a word of praise is due to Mr. Latham, of the Botanic Gardens, Mr. W. Herne, Mr. Stacey, and Mr. Spinks of the Lower Grounds, Aston, who saw to all this. D.

The Liverpool Chrysanthemum and Fruit Show.—The Liverpool Horticultural Society held the annual exhibition of Chrysanthemums and fruits on Wednesday, the 21st ult., under circumstances which promised to be a great success. The number of entries in all the classes exceeded those of any previous exhibition for the past seven years at least, and all arrangements for a successful exhibition were unique and complete. The sun, however, denied his smiling augury to lend lustre to the occasion, and what was still more unfortunate than the mere absence of sunshine, the elements seemed as if by concert to belch forth in angry torrents a continuous downpour of hail and rain. Only those who have some experience of stormy weather on the steps in front of George's Hall (where the exhibition was held) and the corner of Lime Street and London Road will be able to fully appreciate the difficulties the pedestrian had to encounter before reaching the exhibition. The principal attraction on these occasions is of course the Chrysanthemums in cut blooms and trained specimens, and it is no idle compliment to pay to Liverpool growers to say that they out-distance their competitors in the cultivation of this the queen of winter flowers.

In the class for eighteen cut blooms, large-flowered Chrysanthemums, Mr. Tunnington, gr. to Charles McIver, Esq., staged perhaps the finest stand ever exhibited here or elsewhere, perfect in form, substance, and colour, and grown to a day. Mr. J. Roberts was a capital 2d, and Mr. Peers 3d. In the class for twelve cut blooms there was evidently some oversight in making the award, and never was the Scriptural phrase, "the first shall be last and the last first," more truly exemplified than in this instance. To Mr. Pythian first honours were awarded: his flowers were under-sized, two of their number being "absolutely over" and one (Hermine) being wrongly named. Mr. Mease, who was clearly entitled to the prize, showed a highly creditable stand; his flowers were large, well-formed, brilliant in colour, and presented a striking contrast to the seedy appearance of the 1st prize lot. The prizes for six cut blooms were keenly contested by Mr. Leadbetter and Mr. Knott, being awarded in the order named.

Trained specimens were represented in all shapes, reflecting great credit on the ingenuity of the various exhibitors and a striking memorial of the handiwork of the craft. Probably this formality of training has reached its climax, public opinion is already denouncing the working out of any geometrical problem on a family of plants whose natural form of growth is repugnant to distortion in any form. The general exhibition of stove and greenhouse plants, Palms, Ferns, &c., was excellent; whilst Epiphyllums, Poinsettias, fringed Primulas, and Roman Hyacinths were in ample quantity to enable the committee to make a brilliant display all over the hall, every foot of space being admirably lit up with choice plants interesting either for the beauty of their leaves or flowers.
